The conclusions drawn from the analysis are that goitre is twice as common in the country as in towns, that it is more than twice as common in the west of England as in the east, and that it is nearly three times as common in girls as in boys. Roughly speaking, the incidence-rates for towns, although generally lower. confirm the results for the country areas The urban rates are more variable, as Dr. CAMPBELL says, "possibly because the greater uniformity of a town water-supply may minimise or exaggerate the effect of the average water-supply of the villages and smaller towns of the area" The percentage incidence for London, although not given, is stated to be very low, whilst those for Manchester (9 7), Bristol (7), and Birmingham (6 3) are high. Three maps are given showing: (1) the incidence of goitre in school-children in the counties, (2) its incidence in 17 large areas (rural and urban figures); and (3) the death-rate from exophthalmic goitre in the same 17 areas Comparison of the two last shows a general resemblance between the incidence of goitre and the mortality from exophthalmic goitre; in order to obtain a more objective measurement of the correlation Dr CAMPBELL gives a scatter diagram which, although showing no very close agreement, indicates that simple and exophthalmic goitre tend to increase together. The remaining conclusions reached are that goitre is relatively common in the south-west of England (in which Wiltshire and Hampshire should probably be included), in Hereford and most of Wales, in much of Lancashire, Cheshire, Derby, and Nottingham, and in a Midland area comprising Oxford and perhaps Buckingham and Northampton. Goitre is least common in Glamorgan and Monmouth, Essex, Hertford, and Middlesex, and an eastern area running north from Hertford and Essex up to and including Lincolnshire There is no evidence that proximity to the sea coast is a factor of predominant importance Most of the districts where the incidence is specially low and many where it is specially high are on the sea-coast In England, as in most other countries where the incidence of goitre is known, hills seem to play a much more important part than the sea The apparent correlation between the incidence of simple and exophthalmic goitre is of great interest, though, as Dr CAMPBELL points out, it has to be remembered that a proportion of the deaths registered as due to exophthalmic goitre may in fact be due to hyperthyroidism associated with an adenomatous gland

THE MORTALITY FROM INTESTINAL OBSTRUCTION

INQUIRY into the results of the treatment of acute intestinal obstruction has revealed the fact that the mortality of this serious disease has scarcely fallen with the great advances in general abdominal surgery during recent years Certainly, as in every other surgical emergency, the patient's prospect improves in proportion as he comes in good time into the surgeon's hands, but the toxæmia which is the primary cause of the high mortality-rate develops early and renders futile the most skilful operative technique Early operation under favourable circumstances has not sufficed to bring the mortality down much below 20 per cent, while over a large

---

[1] Journal of Hygiene, March, 1927

series of cases it may approach 50 per cent That it should remain almost stationary at this level points to some defect in our knowledge of the pathology of the condition An attempt to clarify the problem was made by Mr B W **Williams** in a recent Hunterian lecture which is printed in our present issue Mr **Williams** points out how the aspect of a patient suffering from acute intestinal obstruction or the ileus of advanced peritonitis resembles very much that of an individual the victim of gas-gangrene The character of the pulse, the cyanosis, the slight icterus, and mental reaction are very similar Indeed, in severe cases of acute septic appendicitis anti gas-gangrene serum has actually been administered with some apparent success by certain French observers Mr **Williams** set out with the hypothesis that in ileus the toxæmia and death which occur in spite of mechanical relief were due to poisoning by *B welchii* He found that this organism, which is an almost constant but not flourishing denizen of the alimentary canal, proliferates abundantly in the obstructed bowel It does not normally grow well in the stomach and large intestine because it is very sensitive to the presence of acid It can flourish in the small intestine, whose contents are alkaline and free from oxygen, but does not get much chance of doing so unless stagnation occurs Favourable conditions, however, prevail in mechanical and paralytic ileus It is not only present in large numbers in the contents of the intestine in such cases, but was found in the vomit of a very large proportion of patients Experiments were also performed which seemed to show the presence of the toxin of *B welchii* in the fæcal contents above an obstruction It is easy to see how absorption by the damaged mucosa could lead to the very grave general condition associated with the later stages of intestinal obstruction or peritonitis, and if, as it seems, the toxin directly paralyses the smooth muscle of the bowel wall, the body would be unable to rid itself of the source of the toxæmia, even though the mechanical block were removed The natural development of these researches was the administration of an antiserum to a series of actual cases of septic appendicitis and intestinal obstruction This clinical test was carried out and appears to have justified the hopes raised by a consideration of the results of the previous researches In a series of 214 cases of obstruction, due to many different causes, the mortality-rate was 24 8 per cent , in a series of similar cases, differing only in the fact that antitoxin was given, the mortality-rate was only 9 3 per cent Mr **Williams** suggests that there may be a further saving of life from prophylactic injection prior to operation, for sudden collapse is not uncommon after the most successful operative relief, due, he suggests, to the sudden flooding of the circulation with a lethal dose of toxin as a result of the relief of strangulation Control of the toxæmia by a lavish use of hypertonic saline intravenously was suggested a year or two ago to the Western Surgical Association, U S A , by Dr T G **Orr**, who also brought experimental evidence in support of his thesis Others have reported favourable clinical results, most recently Dr E P **Coleman**, of Canton, Ill , who has reduced his operative mortality thereby from 50 to 11 per cent A quart of 3 per cent saline is given before and as much, or more, following the operation, with the result of enabling the toxic patient to live until he has recovered from the effect of the surgical intervention These are distinct contributions to our knowledge of very fatal diseases and place within our grasp new weapons against them;

THE FOLLICULAR HORMONE

Double oöphorectomy abolishes the cyclic changes which normally take place in the female genital tract, and it has been concluded that the ovarian influence thus removed is hormonic in nature That this is so is suggested by the experiments of E **Knauer** (1900), who showed that the cyclic changes continue if the ovaries, instead of being destroyed, are merely transplanted to another site in the body Until recently, however, there has been doubt as to which part of the ovaries supplies the hormone Of the various methods employed to localise this function the most direct is the injection of ovarian extracts into test animals, but lack of a satisfactory test for their action made the results inconclusive until, in 1917, C R **Stockard** and G N **Papanicolaou**[1] demonstrated a method of following œstral changes in the guinea-pig by the microscopical examination of vaginal smears It was found that there is, during the cycle, a definite succession of cell types in the vaginal lumen, each type being correlated with a certain phase of œstrus, the identification of these types furnishes reliable data for determining what is happening in the internal genital organs With this accurate method of testing, E **Allen** and E A **Doisy** were able to deal conclusively with the œstrus producing hormone of the ovary They published in 1923 a preliminary report on the results of injecting fresh follicular extracts into rats and mice, and in 1924 a full report[2] of experiments showing that the injection of liquor folliculi into spayed rats and mice induces typical œstral changes, comparable in degree to full œstral development of the genital organs of normal animals They concluded that these injections were a complete substitute for the ovarian hormone—at least in the absence of pregnancy—for they produced in the genital tract the accelerated growth, hyperæmia, and secretion characteristic of the period of œstrus, the changes being as great as those attained in the normal animal under ovarian influences

These observations indicated that the principal ovarian hormone is formed in the follicle, and in the last few years series of experiments have been made which have increased our knowledge further In 1926 E **Allen** and J P **Pratt** published[3] the results of injecting follicular extracts into monkeys and human beings, whose ovaries had previously been removed Growth of the uterus was again found to follow injection and, in women in whom an artificial menopause had been induced, this uterine growth was accompanied by subjective sensations similar to those previously experienced at times of menstruation, though there was no bleeding approximating to that of normal menstruation. Injection was also tried in cases of primary amenorrhœa—that is to say, in girls who had reached the age of 20 without having menstruated Menstruation did not follow this treatment, but again there was an increase in growth in the uterus, though without recognisable subjective symptoms Better results were obtained in girls with irregular and scanty menstruation, an increase being noticed in the amount and regularity of the flow Similar observations have recently been made by L **Brouha** and H **Simonnet**[4] in Paris

The œstrus-producing hormone can be found not only in the follicle but also in placental extracts, and the term "folliculin" should, perhaps, be abandoned in favour of "œstrin," as is suggested by A S

PARKES and **C W BELLERBY** These English observers have studied the problem from a rather different aspect [5] They point out that as œstrus does not occur in either pregnancy or lactation, it is probable that an œstrus-inhibiting mechanism is set up by the persistent corpus luteum which is formed during these periods—a theory which has been put forward by **L LOEB** The exact nature of the mechanism is not clear, but **PARKES** and **BELLERBY** have shown that injection of œstrin during the early stages of pregnancy overrides the œstrus-inhibiting principle and causes the rapid reappearance of œstrus and the termination of the pregnancy The same result is obtained in the later stages of pregnancy and during lactation, but the dosage required is greater in each case They remark that these results may have a possible application to medicine and animal breeding In cows the undue persistence of corpora lutea is responsible for a type of sterility which is now cured in many cases by squeezing out the corpora lutea per rectum It is possible, they think, that the injection of œstrin would override this inhibitor action of the persistent corpus luteum, and as a result lead indirectly to ovulation and to the restoration of fertility. It is suggested, also, that in the human subject a type of amenorrhœa occurs which is due to the failure of the corpus luteum to retrogress and which is analogous to prolonged pseudo-pregnancy In such cases it would seem that the overriding of the corpus luteum by injections of œstrin might lead to the reappearance of the menstrual cycle In any case it is obvious from the facts which have been discussed that the appearance of an active follicular extract has a considerable application in clinical medicine, and a new field of research has been opened up to those who are interested in these problems

THE TREATMENT OF RABIES IN CALCUTTA

THE second annual report [6] of the Pasteur Institute in Calcutta deals with the year 1925, when 5585 patients attended the dispensary, of whom three-quarters went through a course of antirabic treatment None of the 247 Europeans or Anglo-Indians who underwent treatment died of hydrophobia, although 33 of the 3921 Indians succumbed It is, however, made clear in the report that conditions were very much more favourable in the one case than in the other Half the Europeans were no more than licked by the rabid animal, only 17 per cent of them had deep bites, none was bitten by a jackal, and 82 per cent presented themselves at the institute for treatment within a week of contact with the rabid dog On the other hand, in 98 8 per cent of the Indians the skin was broken, 46 per cent were bitten deeply, in 33 per cent the bite was of a jackal, and more than one-third did not reach the institute until a week or longer had elapsed after contact Sixteen of them developed hydrophobia either during the course of treatment or within 15 days of its completion, and these can hardly be considered to be failures of treatment; but the remaining 17, which developed symptoms later than this, are set down as actual failures of treatment The number of cases advised is many times greater than in any of the Pasteur Institutes situated in the hills and shows the real service which has been done to the city by its foundation The work has been carried on under great difficulties in a single room of the School of Tropical Medicine, the whole staff working at high pressure throughout the year, including Sundays and holidays

Annotations.

“Ne quid nimis”

A MODERN TROOPSHIP

ABOUT a week ago the transport *Neuralia* sailed, from Southampton with troops for China, and a representative of THE LANCET was given permission to go over her during embarkation It is difficult to know what a trooper will be like during a passage until one has sailed on her, but it was evident that the standard of comfort in such vessels has risen considerably of late years During the war *Neuralia* was a hospital ship, being first fitted out at Alexandria by the Red Cross, now she has been trooping for three years and has all the fittings that are required and a staff that knows its business. A transport nowadays is not filled to the brim as in former times The men have more space, consequently the messes are less crowded, and in *Neuralia* this means that there are no messes amidships, where the accommodation corresponds to the inside rooms of hotels, or the inside cabins on mail steamers This is a great advantage The hammock plan, too, has been carefully rearranged to ensure that the men's mouths are more than 4 feet from one another so as to minimise the spread of infection by droplets in sneezing or coughing By way of additional ventilation this ship has some air-blowers about her decks; flat electric fans are fitted in considerable number on the troop decks, and there is one in each cabin Though these fans do not bring in fresh air they circulate what there is and utilise the whole of its drying power to the increased comfort of the inhabitants As the R A M C officer in medical charge on a transport is now in charge of the crew and their living arrangements, our representative was allowed to see the accommodation provided for the lascars and this, after the excellent troop decks, he found disappointing “No doubt,” he says, “the men berthed here had each the 72 cubic feet the Board of Trade requires they shall have, and probably they had all the light the Board of Trade thinks sufficient, yet, compared with those others, the lascars' crew spaces can only be thought dark and crowded, though much trouble was clearly taken to keep them clean”

Drinking water taps are on all troop decks and the water is sterilised when necessary The washing arrangements for the troops are very complete, there are tip-up wash-basins with a supply of cold water, and under each basin is a small trough for washing clothes Over the impervious floor of the ablution room are the douches which will be found so useful in the tropics Large canvas baths are also carried in which, when they are rigged up on deck, a man can swim a few strokes There is a dispensary for the troops aft, and a small hospital, while on the detached poop is an isolation hospital of three beds with a cabin for an orderly, here, too, is a steam disinfector It is expected that a quarter of the men will every night be either on duty or sleeping on deck, but actually it is probable that about half of them will sleep on deck once the ship passes Port Said, for it is hot now in the Red Sea The messing scheme promises well For breakfast the men get tea, porridge, and a second course of kipper, fresh fish, or sausage; for dinner they have roast, boiled, or stewed fresh beef or mutton, potatoes, and a vegetable—green for some days after leaving port, and dried thereafter Tea is the same as breakfast but without porridge and in the hot weather corned beef (cooled in the refrigerator) will be an acceptable substitute for sausages For supper there is cocoa and ship's biscuit Every man may have, on payment, a pint of beer with his dinner and there is a canteen At dinner-time every day the orderly officer produces his mess board and adjusts complaints, if there are any

The men embarking our representative states, seemed a more even and, perhaps a sturdier lot than before the war There was no confusion, and what used to be called "language" was not heard, which may have been due to the greater space provided per man At any rate it is clear that the recent improvements in the transport of troops by sea have justified themselves in the lessening of illness, whereas in 1913 there were 631 admissions for illness per 1000 men carried by sea and 1 08 deaths, in 1925 there were but 184 admissions and no deaths at all Thus the R A M C makes progress in its admirable work for the prevention of disease in the Army at sea no less than in the Army ashore

B C G. VACCINE

A YEAR ago we reviewed [1] at considerable length the collected reports, extending over a period of years, of Prof A Calmette [2] and his collaborators on the use of the prophylactic antituberculosis vaccine B C G. This vaccine is prepared from a bovine strain of tubercle bacillus which, at the outset of the immunisation tests, had already been subcultured for a period of 13 years on a medium of glycerinated ox-bile until its virulence had become markedly attenuated and it could be inoculated in the living state without producing harmful effects The vaccine has been administered to laboratory animals and to calves—orally, intravenously, and subcutaneously—and for the past three years has been given by mouth to new-born children in the first fortnight of life It will be remembered also that a series of experiments on the higher apes in a tropical island was undertaken with encouraging results, and gained considerable prominence in the lay press The earlier reports seem conclusively to have demonstrated the fact that the vaccine is harmless, even when given to new-born infants The next point to be established by Prof Calmette was the value of the vaccine as a prophylactic agent This is obviously a more difficult matter requiring much time and patience in waiting for results and collecting records Prof Calmette has now brought together a number of these records [3] in what is for practical purposes a monograph of the subject up to the end of 1926' By this date the number of children vaccinated is known to have reached 21,200 Presumably these figures include those given in the previous monograph a year ago No complete analysis of the whole of these figures has yet been attempted, but several reports of special groups are now given The first of these is by Mr Moine, statistician to the Comité National de Defense contre la Tuberculose, and is concerned only with infants which have been in contact with a tuberculous person or have been living in a tuberculous environment The total number thus investigated is 982 From this figure 13 are deducted because it was found necessary to remove them from their tuberculous environment Of the remaining 969, 882 are reported upon one to two years after vaccination, they show seven deaths from tuberculosis and 72 from other diseases, whilst 87 reported upon more than two years after vaccination show no deaths from tuberculosis It is concluded, therefore, that the mortality from tuberculosis amongst these vaccinated cases in the second year of life is approximately 0 8 per 100 living, and from all causes 8 9 per 100 The mortality in the same age-group amongst children born of tuberculous parents or living in a tuberculous environment is placed by Prof Calmette from available records in various European countries at 26 per 100 living By way of comparison statistics recorded by Dr Ott, of the Hygiene Department of the Seine-Inférieure, and by Dr Morlot, of the Dispensaire Brouardel of Havre, are given These and other reports from Belgium, Rumania Greece, Algiers and Indo-China confirm, in the main, the statistics of the Comité National The monograph also contains reports of an experiment in prophylactic vaccination of calves on an infected farm, some experiments upon laboratory animals, and a long report of a Ukraine Commission on the subject by Prof S Zlatogoroff The work on the infected farm of Gruville shows that at the commencement of the experiment in 1921 41 7 per cent of the cattle were reactors to tuberculin whilst there had been unmistakable post-mortem evidence of tuberculous infection From 1921 to 1926 B C G vaccine was administered to the calves born each year At the end of 1926 the position was that 11 animals of the original infected stock still remained 58 born since the experiment and vaccinated shortly after birth had been added to the herd, 30 had been slaughtered for commercial purposes without evidence of tuberculosis being found, whilst 22 had died of diseases which were found to be non-tuberculous No precautions against tuberculosis other than B C G vaccination had been adopted on the farm during the experiments Prof Calmette sums up this work in his own inimitable way—"simplicité, innocuité, efficacité" We have already indicated in the previous review our opinion that much painstaking research is still required before a final conclusion can be drawn The need is not so much for piling up large numbers of statistics as for intensive research on those patients and animals already vaccinated. In the case of the infants a systematic scheme of after-care with periodic re-examinations is obviously required So far the post-mortem evidence on the cases (children and animals) which have died appears to be weak as regards inclusion in the non-tuberculous group

VITAMIN D IN WINTER MILK

INTERESTING attempts are being made to improve the value of winter milk in vitamin D. It is an unfortunate dispensation of Nature that just at the winter season, when the human being is deprived of ultra-violet light, many of his chief articles of food also decline in their content of vitamin D from the same cause The animals and plants growing in these islands are also deprived of ultra-violet light in the winter and their value as food accordingly diminishes The diminution is most marked in the case of cow's milk and its derivatives and constitutes a serious problem in the feeding of infants and young children, particularly in the north, where winter conditions of life, both for children and cows, last so much longer than in the south The prophylaxis of rickets in such young children might be secured by the universal administration of cod-liver oil, but though it is found possible to secure a very wide use of it, such a *universal* consumption seems unattainable Nor can ultra-violet light be distributed generally, and in any case universal prophylaxis for the winter would be more naturally accomplished by dietetic means A distinct step towards that most desirable goal has been made in the work of Dr J. Golding, of the National Institute for Research in Dairying, in cooperation with Miss K M Soames and Dr S S Zilva [1] of the Lister Institute These workers have been successful in raising the vitamin D value of cow's milk by feeding the cows with cod-liver oil. Such a means of improving the vitamin D content of milk should add little to the price of the milk and compare favourably, as regards the cost of production, with direct irradiation of the cow The latter method is being practised by Prof C Pirquet [2] in Vienna, where the problem is an even more serious one, since the cows which provide the milk for the city are kept in stall all the year round, and the milk given is consequently always a winter milk in its content of vitamin D Prof Pirquet has had some very promising results, both with animals and children, when using this milk, and though the method is at present experimental—it has only been applied to two cows—it would be easy to apply it to all the cows, some 20, in his model stall The mercury-vapour quartz lamp is movably suspended from the roof and at present only travels as far as the second cow, but it could easily be made to travel the whole length of the stall With Viennese conditions and prices this method has not been found too expensive Attempts such as these are encouraging and point, we hope, to a time when it shall be compulsory for nursery milk, if not for all milk, to be produced in such a way that its vitamin D content can be guaranteed to reach a definite standard At the same time it is essential that the cost of the milk should not be materially increased

THE TEACHING OF BACTERIOLOGY IN LONDON

THE supply of young and well-trained bacteriologists is unequal to the demand for them both in this country and abroad, and this deficiency must be regarded as partly due to a lack of facilities for the training of suitable students These facilities may be provided either before or after graduation Bacteriology may be recognised as a subject for a science degree—as is now done at several of the universities—and thus form an important part of the undergraduate's training, at Cambridge a course of bacteriology can be taken, with pathological work by those who go on to the second part of the Natural Science Tripos Alternatively, the instruction may be given after medical qualification, and for this purpose it is convenient to provide a whole-time course leading, perhaps, to a university diploma In London, especially, it is desirable that such courses should be made available, if only as part of the scheme for making London the main centre of post-graduate education within the Empire It is satisfactory, therefore, to learn of the opening in October next of the Division of Bacteriology and Immunology of the new London School of Hygiene and Tropical Medicine The board of management has decided to start the work of this division in temporary premises in Gordon-square pending the completion of the school buildings, and during this interim period a whole-time post-graduate course in bacteriology will be given under the immediate direction of Prof W W C. Topley who is to occupy the university chair of bacteriology and immunology in the School It will not be possible to arrange instruction for candidates for the Diploma in Public Health until the accommodation to be provided in the main building becomes available In the meantime inquiries about the bacteriological course should be addressed to the Director of the London School of Hygiene and Tropical Medicine, at 37, Torrington-square W C 1.

THE HAIRMYRES TUBERCULOSIS COLONY.

THIS institution chiefly serves the middle ward of Lanarkshire, though patients are admitted from other parts of the county and from outside The report of the physician-superintendent Dr James Johnstone, shows that 306 patients were discharged during 1926 Of these 149 were pulmonary and 133 non-pulmonary tuberculosis, and the remaining 24 included three cases of syphilis two of bronchitis one each of bronchiectasis and gastritis, and 17 in whom no tuberculous lesion could be detected Miners exceeded other occupations among the patients, mining being the chief industry of the area Of the 149 pulmonary cases, 51 belonged to the early maturity age-group (between 25 and 45 years) 59 per cent had been ill for over four years and 75 were in the Turban-Gerhardt stage I Of the 75 stage I patients 24 showed arrest of the disease of the 47 stage II, 6 and of the 27 stage III none The average duration of stay was 300 days for stage I 330 for stage II, and 247 for stage III, and 21 per cent had a positive family history The 133 non-pulmonary cases included 78 of cervical glands and 20 abdominal cases, and the average stay for children was from seven to eight months one year being the duration aimed at About 30 per cent gave a positive family history. The discharges included 52 ex-Service men and 102 of the 125 adult males discharged were registered for training Thirteen per cent of the adults admitted gave a positive Wassermann reaction as compared with 5 per cent in the previous year

It was a good summer for heliotherapy and satisfactory results were obtained among the children. Some 33 patients had artificial light treatment, the cases which did best being lupus, glands with discharging sinuses and tuberculous abscesses of the soft tissues (scrofuloderma) Dr Johnstone comments on the fact that the more advanced broken-down glands did better than the enlarged glands which had not broken down. For 29 the carbon arc was used, for three the mercury vapour, and for one both Dr Johnstone prefers the polar white flame positive carbon with the solid ordinary negative carbon, when used in the open carbon arc lamp He is inclined to recommend the installation of both types of lamp for clinics, the carbon arc for general and the mercury vapour for local treatment The average number of scholars in the open-air school was 93. In the colony departments, the working hours varied from two to six per day; the number of patients enrolled for training was for gardening 46, for the forest nursery 65, for the poultry farm 63, for the piggery 24, and for the institution workshop 11 The guinea-pig department had a heavy mortality among the young stock from an obscure disease with diarrhœa as the chief symptom

The industrial workshops had 24 trainers in the motor-repairing department, 19 in cabinet making 11 in boot repairing, and 9 in basket making As regards the first, the two motor lorries of the colony are kept in order, while the Ford Motor Company kindly lends the latest type of chassis for the training; and the three trainees who entered for the certificate of the Scotch Automobile Club were successful As regards the last, it is noted that there is a dearth of good basket makers in Scotland and that pigeon baskets, for example, can only be procured in England Approximate figures are given of after-results of training Thus, of ten men trained in cabinet making, four are working at the trade, while two out of four, five out of ten, and 16 out of 20 are now working at the basket making boot repairing, and motor repairing respectively for which they were trained

SARCOMA OF THE RECTUM

ACCORDING to Dr J H Weeks, of the Lankenau Hospital Philadelphia who records an illustrative case,[1] sarcoma of the rectum is an exceedingly rare condition Among 100 malignant rectal tumours Hartmann and Quenu did not find one sarcoma; inquiries at 150 of the principal hospitals and museums of Great Britain and Ireland produced only two cases whilst among 500 patients operated on by D'Hochenegg from 1900 to 1907 for malignant growth of the rectum only four had sarcoma the growth being of the melanotic type in two of these Although approximately 100 cases of sarcoma of the rectum have been recorded, the number would, in Dr Weeks's opinion, be reduced by over a half if the questionable cases were excluded The growth usually begins in the submucous coat as a small, nodular mass movable on the muscular coat and absolutely independent of the mucosa which is usually intact As it progresses it tends to invade the mucosa, when ulceration frequently occurs Sarcoma is, as a rule, hard in consistence until ulceration takes place when it becomes soft and spongy. Rectal sarcoma is much commoner in men than in women in the ratio of about 5 to 1; the ages recorded range between 35 and 81 years The symptoms differ only slightly from those of carcinoma, but the latter ulcerates more quickly, gives rise to cachexia sooner, involves the lymphatics and is practically never pigmented Sarcoma generally causes less pain than carcinoma and the spread is by the blood stream rather than by lymphatics X rays and radium, Dr Weeks considers are valueless in the treatment, owing to the rapid and fatal metastases which may take place, an early and very radical operation is indicated His own case was that of a man, aged 40, who in spite of repeated operations and X ray treatment died of general sarcomatosis seven months after appearance of the first symptom.

WANTED, A SCIENTIST

AN advertisement in THE LANCET this week states that, certain preliminary work with children of 4–7 years of age having been done successfully at the Malting House School, Cambridge, the directors of the school propose to make a full-time and long-term appointment of a suitable man to introduce young children to science and scientific method The directors are prepared to pay a salary that will enable a successful candidate to leave his present occupation whatever that may be, an openhanded policy that indicates awareness that the search for the man may be a difficult one The advertisement sets out the nature of the problems which he will have to tackle, from which it appears that the pedagogue—using the word in its exact sense—will need to understand the urges of the childish mind, that he may discover how these can be best converted into a controllable instrument of organised thought The use of apparatus specially designed for children is considered a necessity, and this must be of a sort that lends itself to any modification that is required by the growing intelligence of the child, the methods of instruction are to be developed alongside of the developing child, his immature mental processes being studied, and the demands of reality being graded to his capacity The directors of the Malting House School state that while they are willing to consider applications for the post from the teaching profession, they look rather to a man who has already engaged in some sort of scientific work and whose reactions to children have not been influenced by the necessity of teaching them Sir Ernest Rutherford, P R S, Prof. Percy Nunn, and Mr J B S Haldane will assist in the final selection of a candidate for a highly original appointment

ARSENICAL CONTAMINATION OF FOOD

SINCE the great "arsenic in beer" scare of thirty years ago various sources of arsenical contamination of food have from time to time come to light A not very obvious source of this unpleasant element was pointed out in 1924 by G D Elsdon, who examined 51 wrappers of proprietary breads and found arsenic in nine of them No enterprising daily journal has taken up this matter under the attractive headline of "Death in Wrapped Bread," but the question of arsenic in wrappings has been further investigated by Mr T Hedley Barry, who has published a paper in the current number of the *Analyst* on Arsenic in Printing Ink He points out that the source of arsenic in the wrapping papers was probably the printing ink of the labels, which were blue, purple, and green, and as more brilliant colours are used in the wrapping of confectionery he has investigated some of the papers used As confectionery is frequently of a moist and sticky character and is largely consumed by children who are as frequently of a similar character he wisely suggests that the limit of arsenic should be almost as stringent for the wrapper as for the wrapped The practice of manufacturing confectioners is usually to stipulate from the printer that arsenic-free colours shall be used, and he in turn passes on this requirement to the ink-maker But arsenic may be present in the paper itself, and this may be a much more important matter when the amount of printing is small The limit of arsenic proposed for beer—namely, 1 in 700,000 or 1/10 gr per gallon—would be impractically rigid for printing materials, zinc oxide, for instance, of B P quality, with its limit of 1 in 100,000, would not pass this test It appears that the wrapper seldom weighs more than 5 per cent of the total weight and that about 0 5 g per square metre is about the limit of ink on paper Mr Barry considers, having regard to these facts, that ink containing less than 1 part of arsenic in 50,000 of pigment may be used unconditionally, that those containing between this limit and 1 in 20,000 may be used with the less arsenical ones, and that none exceeding this limit should be used at all A variety of colours examined fell mostly in the first class Arsenic has been found, as is well known, in imported American apples Lendrich and Mayer (2 Unters. Leitungsm, 1926, lii, 441–457) have found arsenic in dried pears (unpeeled) and even in partly peeled apple-rings It is possible to be too exacting in requirements as to the quality of food, but these various sources of arsenic, like those of boric acid and similar preservatives in foods, need careful watching It may be that the day is far distant when the poisoner will kill his victim by means of a carefully chosen diet no one article of which comes within the scope of the Poisons Acts, but the detection of arsenic in food products and their adjuncts does point to the possibility of injury to health of a kind to baffle the physician as to its origin and nature and to complicate the action of the drugs he may see fit to administer. So far as can be seen, it is likely as new methods of treating, packing, and distributing food products are adopted new sources not only of arsenic but of other poisonous substances will need to be guarded against. This is a matter on which the Ministry of Health and the medical profession should keep watch.

THE ENGLISH PUBLIC-HOUSE.

THE amenities offered by the public-house have been made the subject of constant strictures in the press, and not long ago in these columns the suggestion was made by a writer that it was to the interests of the extreme temperance cause to see that no improvements took place, because with the betterment of the public-house there would disappear one of the most obvious arguments against the use of alcohol In Carlisle there will shortly be opened a model place of refreshment in the heart of the town, replacing an old public-house, and it seems that the new establishment may serve as an example of what can be done to render the public-house a place of pleasant resort and a useful centre for the promotion of social activities The premises are thoroughly well equipped and arranged in such a way that both sexes can use them either in common or reserved rooms, but the character of the public-house will be preserved—that is to say, that, while such adjuncts to drink as bread-and-cheese, sandwiches, and cake will be provided, there will be no restaurant. The house will, in short, be one "licensed for the sale and consumption on the premises of intoxicating liquors," and, while not pretending to be anything else, will be a demonstration of the fact that the business of the public-house can be conducted with general propriety and with comfort to all concerned Those who know anything about public-houses, and those who have actually used them, know that this is not a new thing, and that the wholesale denunciation of all public-houses, because some of them are revolting places, is unjustified For the benefit of persons who have been led to think that the lowest type of drink-shop is typical of all public-houses, we may commend a little book which has just appeared, describing fully the English public-house [1] Mr Selley does not enter the arena of controversy upon the drink question He states that the main business of public-houses is concerned with the sale of intoxicating liquors, and then details the results of a long investigation into the various types of public-houses to be found in typical communities and localities, and into the uses made of them by their frequenters The efforts towards reform made by "the trade" itself are set out, and in particular the substitution in Carlisle of a large measure of State ownership for private ownership is shown to have been attended with obvious advantages The book is written throughout with studious moderation, and the main conclusion come to is one which will receive medical endorsement Acknowledging that trade in liquor must be a dangerous business, the author finds that the safeguards of laws and regulations set up by the community do not balance the pushing power of private profit-making And while there are many well-managed public-houses, there is a preponderating quantity of drink-shops where no social attractions of any sort are offered and where the inmates of the hospital and the burial ground are recruited

VACCINE TREATMENT OF ENTERIC FEVER

THE value of T A B vaccine in prophylaxis is hardly in dispute At the General Hospital in Rangoon Major M L Treston has continued his investigation of the effects of the injection of enteric group vaccine in the treatment of enteric fever[1] His material consisted of 151 cases of enteric fever, but in the absence of controls it is difficult to gauge precisely the significance of the results In this series there were five deaths which the author regards as less than might have been expected with other lines of treatment In 139 cases the fever is said to have been curtailed but details are not given The vaccine was injected hypodermically commencing with a dose of minims ii, increased at each injection by minim i up to a maximum of minims x The strength of the vaccine is not stated Major Treston comes to the conclusion that vaccines are of undoubted use in the treatment of enteric fever in that they curtail the pyrexia, limit toxæmia, and prevent complications The same conclusions in regard to the therapeutic use of enteric vaccines in the treatment of the enteric fevers are arrived at by Dr. K D Fairley in an article originally published in the *Medical Journal of Australia* and now republished in Vol II of the Collected Papers of the Walter and Eliza Hall Institute of Research, Melbourne Dr Fairley injected the vaccine intravenously for three or four days in succession, commencing with a dose of from 50–120 millions and working up to 200 millions No ill effects were noted in any case, not even in that of a boy of 14 who received 16,000 million bacilli in one dose by mistake Analysis of the tables points to the conclusion that the treatment is of less value in children than in adults Whereas in the adult series the total period of pyrexia is 26 days in the vaccine treated as against 36 days in the non-treated the corresponding figures in the case of children are 34 and 30, and whereas in the adult series the death rate is 7 5 per cent in the treated as against 10 3 per cent in the non-treated cases, in the case of children the corresponding figures were 13 3 in the treated as against only 6 7 per cent in the non-treated cases In this respect the author's figures hardly seem to bear out his conclusions

SUPERFICIAL RADIUM THERAPY

THE variation introduced by Mr Hayward Pinch, the Director of the Radium Institute, in his series of annual publications makes each volume of independent practical use, while the series as a whole already covers most of the ground of radium therapy This year all those maladies which affect the glabrous skin, mucous membranes or subcutaneous tissues and respond favourably to exposures of Beta radiation of comparatively short duration are discussed in a handy volume of 64 pages, divided into 14 chapters Since knowledge of the histology of the skin and its appendages is essential to the correct appreciation of the pathological changes a short description of the normal microscopical appearances is given, and the brief summary of ætiology and pathology which accompanies the clinical account of each condition will help the reader to understand the reasons for the duration and character of the exposures advised Hypertrophies, new growths, and congenital affections of the epidermis occupy the first part of the book, new growths of the corium follow, and the other chapters are concerned with angiomata inflammations of the skin; affections of the hair and of mucous membranes

Radium is said to be of great use in the early stages of Dupuytren's contraction, in favourable cases the fibrosis is greatly diminished, the contraction lessened or abolished, and complete extension of the affected joints rendered possible The patient should be warned of the chances of recrudescence As to capillary and cavernous nævi, some of the plates show excellent results in unsightly lesions which would obviously have been too large for successful treatment by carbon-dioxide snow The cosmetic side of radium treatment is further exemplified in hypertrichosis in women If the areas affected are extensive the treatment of the individual hair follicles by electrolysis is so tedious and trying that patients are apt to become disheartened and to refuse to persevere with the process In such instances Mr Pinch holds that it is justifiable to resort to radium, since excellent results are often obtained by its use Treatment must be conducted with caution, otherwise telangiectases may appear later over the areas irradiated Three exposures with applicators containing 0 25 cg. of element per square c cm, screened with 1 mm of silver should be given on each of three successive days, and repeated at intervals of from four to five weeks, three series of exposures in all being administered The duration of each exposure varies from four to six hours, according to the density of the hair growth A gradual atrophy of the hair follicles is thus induced, the hairs fall out and rarely if ever reappear Phototherapy is more favoured by dermatologists than is treatment by radium in certain forms of tuberculosis of the skin notably lupus vulgaris, but Mr Pinch finds that small isolated patches which have proved resistant to other methods often respond well to radium. A bibliography concludes the handbook, which is published with the authority of the Committee of the Radium Institute, and will be supplied free to any medical man on demand.

DR. H H DALE has been selected as a Crown nominee on the General Medical Council in succession to Sir Nestor Tirard

---

A Congress of Tropical Medicine will take place in Cairo from Dec 15th to 24th, and there will be found on p 952 an account of the preliminary organisation The Congress will deal with subjects ranging from diseases of temperate countries to those of a particularly tropical nature, and the sections include the whole range of medicine, surgery, and veterinary surgery There will be an exhibition displaying the technical applications of art and science to the various branches of medicine Conditions under which facilities of travel and reduction of fares are available can be obtained from Dr Zeitoun, 32, rue Gay Lussac, Paris, and Dr J Khouri, 4, rue de France, Alexandria The titles of communications intended to form parts of the sectional conferences must reach Dr Zeitoun, with resumés before Oct 1st

---

THE lecture on May 5th in the course on Pathological Research in its Relation to Medicine being held at St Mary's Hospital, will be delivered by Dr Carl Prausnitz professor of hygiene in the University of Breslau The subject is Experimental Researches on the Nature of the Bacteriophage Prof Prausnitz has convinced himself that the bacteriophages are really living organisms preying on bacteria, and will set out the evidence which has led him to this conclusion The lecture will be delivered at 5 P M in English by Prof Prausnitz, who was educated in this country The lectures in this course are open to all members of the medical profession and to medical students without fee

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions

CCXXI.—TREATMENT OF HAY-FEVER.

HAY-FEVER, as is well known, is a paroxysmal rhinorrhœa caused by a sensitiveness of the patient to grass pollen This pollen affects the hay-fever patient in the eyes and mucous membrane of the nose and throat because only in these situations can pollen get into contact with his circulating blood. Grass pollen plus the serum of a hay-fever subject makes a poison-mixture for man, causing serous exudations and œdematous swellings in whatever tissue it penetrates, hence the symptoms of hay-fever The pollen cross-fertilising the grasses is air- not insect-borne, it will travel many miles on light summer breezes and much further on a strong wind. In such a grassy land as England it is difficult to escape from the pollen cloud which covers the country from about May 20th until July 15th These dates vary a little according to the weather and become slightly later as one travels northward towards Scotland, but the commencement and finish of the pollen varies less than one would expect because vegetative processes depend more upon daylight than upon temperature, and with the pollen cloud the hay-fever season begins and ends

The specific diagnosis—i e, that the paroxysmal rhinorrhœa is caused by grass pollen—may be made in two ways —

1 The rhinorrhœa must coincide with the pollen cloud If the symptoms begin much before May 20th or last much after mid-July, then either the case is not one of hay-fever at all or there is some other complicating factor which must be detected if successful treatment is to be given

2 The disease can be produced artificially, but only in a hay-fever subject, by bringing a minute quantity of the pollen into contact with the sufferer's plasma This can be done quite easily in the eyes, nose, or throat, or, indeed, any mucous membrane, but as a diagnostic test it is better to scratch down through the hard dry epidermis, say of the forearm or of the leg, and to place either pollen, or better still, an extract from pollen, on the abraded surface Nothing will happen in a normal person, but the hay-fever patient will show within a few minutes a weal at and around the area of abrasion, and surrounding the weal there will be an erythematous blush This constitutes the well-known skin reaction for hay-fever It can be produced at any time of the year so long as a supply of grass pollen is available

It follows from what has been said in the first paragraph that the serum of a hay-fever patient, when mixed with a little grass pollen, can be tried out as an urticarial mixture by injecting it into the skin of any normal man

Treatment may be prophylactic or therapeutic Prophylactic treatment consists (1) in avoidance of the pollen, or (2) in desensitising to grass pollen by inoculation

Avoidance of Pollen

The pollen grains are of considerable size, something like 20 μ it is therefore possible—though seldom practicable—to filter the atmosphere of any room by arrangements less elaborate than those used in Prof Storm van Leeuwen's "asthma chambers" in Leyden; cotton-wool is a sufficient filter Even when no special precautions are taken, a quiet dust-free room, with windows closed, gives comparative freedom from pollen The well-to-do sufferer can fly the country during the summer months but it will need a good stretch of salt water to give absolute safety if the wind is blowing strongly off shore

The amount of pollen and therefore the intensity of symptoms, will be mitigated by (*a*) distance from a hay field, (*b*) any considerable altitude, (*c*) dull or showery weather, and per contra bright sunny weather, hay fields, river valleys, and travelling by railway or motor will increase the symptoms by increasing the pollen

On special occasions—e g, during a motor run in the country—the danger points can be protected (1) the eyes by closely fitting goggles, (2) the nose by tufts of cotton-wool or small linen filters in the nostrils (both of these devices are very irksome), (3) the throat by strict nose-breathing

Whatever the patient may try it is difficult for him to avoid the pollen and yet retain the common amenities of life.

Prophylactic Desensitisation (Leisurely)

(*a*) Prophylactic desensitisation can be made by subcutaneous injections of a grass pollen vaccine The method which has been used since 1910 is to give weekly injections, commencing in March if possible, and continuing right up to the commencement of hay-fever when they must be discontinued or if necessary replaced by therapeutic (smaller) doses For the purpose of measuring doses of pollen vaccine one "unit" is taken as equal to the amount of extract which can be obtained from one-millionth of a gramme *Phleum pratense* pollen It is as well to begin the prophylactic course with some rather small dose, say from 10 to 60 units of pollen, according to the intensity of the hay-fever in previous years or judging by the skin reaction From this amount the dose can be quickly increased at the weekly reinoculations till something between 200 units in the more sensitive cases and 500 units in the less sensitive is being given regularly. If after any of these inoculations there is a reaction in the patient—either pain at the site of inoculation, or still more important, a general urticaria, angioneurotic œdema, or asthma, then the dose is too large or has been increased too rapidly In either event it is better to go back to a smaller dose, the optimum inoculation being a little less than that which causes a reaction With reasonable care seriously unpleasant reactions are very rare and can be counteracted by subcutaneous injections of adrenalin—say 0 2 to 0 3 c cm of the 1/1000 solution If a reaction is in doubt it is better to continue with the same dose till the doubt is settled

Prophylactic Desensitisation (Intensive)

(*b*) In recent years an intensive course of prophylaxis has been in use, following the plan which has been so successful in dealing with other sensitisations —e g, horse asthma In this intensive course the injections are made every day or as frequently as is practicable and the dose is increased as rapidly as is compatible with the absence of reactions This may in the end prove to be the more effective method because it more closely follows the daily needs and idiosyncrasies of the patient, and because it need not be started so early in the season On the other hand, it makes more demands on the time of the patient and certainly more on the judgment of the inoculator

Commencing with a safe dose—say from 10 units for the very sensitive to 50 units for the only slightly sensitive patient—the dose is increased by 50 per cent, or even 100 per cent at first and then by a less percentage as it gets larger or a general reaction becomes more feared A pronounced reaction can be counteracted by an injection of adrenalin and is followed by a much reduced dose

As an illustration of how the intensive course is likely to run, here is a hypothetical list of pollen injections The patient is supposed to be very sensitive therefore the initial dose is very small One or two of the injections are supposed to have been overbold and the consequent reactions will be seen to have affected the succeeding doses For a less sensitive person the initial dose might have been larger the increase of doses perhaps more bold, the final doses considerably stronger and, if necessary the course might have been continued longer May 1st is a reasonable date for the commencement of an intensive course

May 1st 10 units, May 2nd: 20, May 3rd 30; May 4th: 45, May 5th 60, May 6th: 90 (strongish reaction, 0·25 c.cm. of adrenalin 1/1000), May 7th: 50; May 8th. 70; May 9th 100, May 10th: 140; May 11th. 200 (slight reaction), May 12th 200 (very doubtful reaction), May 13th 200; May 14th 250; May 15th 320; May 16th: 400; May 17th. 550, May 18th. 700, May 19th: 850 (doubtful reaction), May 20th 900, May 21st. 1100, May 22nd: 1300; May 23rd: 1500 units. Here a spell of fine weather is supposed to have started the pollen cloud and so have made any further *prophylactic* treatment imprudent for this very sensitive patient.

Therapeutic Treatment

1. After the commencement of the pollen cloud specific *desensitisation may still be* practised, but as with other forms of vaccine therapy the doses must be much smaller than for *prophylaxis*, *it may be* impossible to give more than 2 to 5 units, it is seldom necessary or prudent to give more than 100 units for a dose. As in prophylaxis a "reaction" is to be deprecated. The size of dose must be estimated from (*a*) the sensitiveness of the patient as judged by his past history or from his skin reaction, (*b*) the condition of his eyes and mucous membrane at the time of inoculating, and (*c*) the reactions, if any, from past doses. The intervals between doses vary with their size from perhaps, 24 hours with the very smallest up to say, a week for the largest. This treatment has, in the writer's experience, failed dismally with some people, but with others has been so strikingly successful that they declare they will not be bothered with prophylaxis for the future.

2. Shock doses are as *applicable to hay-fever as to* any other of the asthma-urticaria group. If immunity is evolved in the business it is certainly non-specific for almost everything imaginable has been used as antigen: tuberculin, typhoid vaccine, peptone, milk, the patient's own blood reinjected intramuscularly, even sulphur emulsified in oil. The object is to cause a shock with a rigor or two, and in the *writer's opinion* the effect is by suggestion. The method is not popular and is not advocated here.

3. Polantin is an anti-pollen serum from immunised horses. Applied locally it gives temporary relief to slight symptoms, but seems unable to help the more severe cases. It is less used now than in former years.

4. Avoidance of pollen. This has been spoken of generally under *prophylaxis*. Lotions (e.g. warm normal saline) wash away pollen grains, and thick ointments protect the underlying *mucous membrane* but cannot be made to coat all the sensitive surfaces. Cauterisation substitutes cicatricial tissue for mucous membrane and in skilled hands any specially sensitive spots can be treated in this way. Carbolic partly kills and partly anæsthetises the mucous membrane.

5. Anæsthetics will temporarily deaden the intolerable local itching, sprays of cocaine, morphia, anæsthesin, &c., may be instanced, but no medical man need be told the difficulties, dangers, and limitations of such treatment.

6. Adrenalin, to a lesser degree pituitrin or any proprietary combination of these gland products, are in a class by themselves. They have a specific action on all the asthma-urticaria syndrome, checking the symptoms and affording *instant* though transient relief, whether injected hypodermically or applied locally. For hay-fever they can be administered as a spray of the 1/1000 adrenalin or a lotion containing a tenfold dilution *of the same*. Such applications seem to be free of bad after-effects and to lead to no "habit."

7. Suggestion treatment cannot be eliminated when dealing with any of the asthma-urticaria syndrome, least of all in hay-fever. It is well in the writer's mind that single doses of a pollen vaccine sometimes act miraculously in this way. It is more than probable that cauterisation of the nose, once so fashionable, *owes much to this* factor of suggestion. Anything associated in the patient's mind with cause or cure of hay fever will act accordingly. There seems to be no evidence that an abnormal *mentality plays* any part in producing hay fever.

For therapeusis small inoculations as described in No. 1 above are advisable combined with any palliative treatments which may help but in really serious cases strong prophylactic measures are necessary.

MEDICINE AND THE LAW.

Unusual Procedure in Court of Criminal Appeal

At its last sitting before the Easter vacation the Court of Criminal Appeal dealt afresh with the case of William Knighton who, as previously stated in this column, had appealed against a conviction for murder at the last Derbyshire Assizes. At the original trial the defence was insanity arising out of epilepsy. On March 21st the Court of Criminal Appeal was invited to substitute for the verdict of "guilty" a verdict of "guilty but insane." The Court declined *to do this*, and announced that, as the issue of insanity had been raised at the original trial, it would not listen to any fresh evidence of insanity but would leave that matter to be determined by the Home Secretary. Subsequently the case was reopened, the Home Secretary referring it back to the Court of Criminal Appeal under Section 19 of the Criminal Appeal Act of 1907. This unusual procedure did not amount to a re-trial of the case, but it gave the appellant a chance to produce new evidence. Section 19 of the Act says that nothing in the Act shall affect the Royal prerogative of mercy; it then proceeds to make the machinery of the Act available in two cases for the purpose of disposing of petitions for the exercise of that prerogative. The Secretary of State under the section may, upon a petition for mercy, do either of two things. First, he may refer the whole case to the Court of Criminal Appeal to be heard and determined as if it were an appeal under the Act in the ordinary way. This alternative was not possible in Knighton's case as his appeal had been before the Court of Criminal Appeal already. Secondly, the Secretary of State may refer to the Court any point on which he desires assistance. It was under this latter power that the Home Secretary acted. The appellant's new evidence—that of his sister—was produced but was not accepted by the Court; the appeal was therefore dismissed a second time. Nothing was said to disturb the practice of the Court of Criminal Appeal *in respect of its* refusal to hear any fresh evidence on appeal if that evidence relates to the defence of insanity and if the issue of insanity has been raised by the defence at the original trial. The Court of Criminal Appeal is evidently unwilling to listen to a succession of mental specialists in murder appeals; it leaves the issue of insanity to the Home Office experts. Its practice in this respect is however, open to criticism in that it discriminates against the reception in court of a particular kind of evidence—namely evidence of insanity—and thus leaves the appellant to take his chance before a departmental rather than a judicial tribunal.

Law Reports and Recent Restrictions

Knighton's case illustrated the recent restriction upon the publication of law reports. In the course of her statement, the appellant's sister gave certain evidence of a sexual character. The *Times*, in its report, remarked that part of this statement appeared to be within the intention of the recently passed Judicial Proceedings (Regulation of Reports) Act, this part was therefore excluded from the report. It may seem strange that a law report in the *Times* should be affected by the recent Act, seeing that the Act has a saving clause in favour of bona fide law reports and seeing that the *Times* reports are all written by barristers and are accepted in all English courts as of full and proper legal authority. But the Act is so worded as to protect only two classes of law reports: one class *includes* any publication of a technical character bona fide intended for circulation among members *of the* legal or medical professions, the other class includes any matter in a separate volume or part of any bona fide series of law reports which does not form part of any other publication and which consists solely of reports of proceedings in courts of law Thus the law reports in the columns of a daily newspaper, however carefully, authoritatively, and unobjectionably prepared and printed, obtain no protection The omission was not a serious matter in the case under discussion, since the Court found the evidence unworthy of belief, but cases may arise where such omissions may be unfair to one of the parties as well as destructive of the value of the report of the proceedings Admittedly the Act was imperfectly drafted It contains, for instance, a list of the sole particulars which may be published in reporting a divorce case The names of the parties and witnesses may be reported but not, apparently, the names of judge, counsel, or solicitors; the apparent omission of the judge's name is the more remarkable since his summing-up may be given in full

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.

Over-prescribing under the Insurance Acts

WHERE the fund is limited every reasonable care must be taken to get full value for the money spent This is all that the "checking bureau" means It has worked in Scotland with much success from an early stage in the organisation of National Health Insurance But there has been, from time to time, much heart-burning It is not an agreeable duty for a practitioner to sit in judgment on his fellow practitioner's prescriptions, and I have never heard that any local panel committee enjoyed the job Yet there is no doubt whatever that the general effect of the checking system and the frequent inquiries by the doctors and officials concerned in the administration of medical benefit has been to improve the level of prescribing Probably over-prescribing—which simply means the use of expensive drugs when equally good but cheaper drugs are available—is largely due to defective teaching It must be embarrassing when a professor charged with the scrutiny of prescriptions finds that some of his own favourite prescriptions are among those pilloried as "excessive" by the checking bureau But the explanation is simple Whilst the expense of a drug bears no relation to its therapeutic effect, nevertheless, if "panel" work is an integral part of our domiciliary medical service, the question of expense is very relevant to practice Recently efforts have been made to bring before the medical profession the methods of avoiding expense by selection of drugs, and by careful attention to quantities dispensed, but obviously there is a recurrent irritation among the insurance practitioners It is reported that appeals "against fines amounting to £370 are to be made by eight of 13 Glasgow panel doctors who were surcharged following allegations of over-prescribing" It is sometimes said that insurance patients get one quality of drugs and private patients another, no such distinction is involved in any regulations under the Insurance Acts Whether the machinery for investigating so-called over-prescribing is the best for its purpose is another question The original intention was to enable the medical men themselves to act as checkers of each other's prescribing

Nursing at a Maternity Hospital.

Although an amalgamation of the Simpson Memorial with the Royal Infirmary has been arranged, the new accommodation cannot be ready for some seven years Meanwhile the work must be carried on and there is an acute financial difficulty, the main immediate cause of which is a change in the period of training for midwives This has caused a marked falling off in the supply of pupil nurses, and in order to maintain the nursing staff even at a minimum standard it has become necessary to offer free training to pupil nurses who have had their general training Hitherto pupil nurses have paid fees and the giving of free training to the majority of its pupils will mean an actual and immediate loss to the Edinburgh Maternity Hospital of £2000

Prof George Robertson, President of the Royal College of Physicians of Edinburgh, at the recent meeting of the hospital dealt with some fundamental points of hospital administration Everyone, he said, would approve of the directors' decision to give free training to all pupil nurses who had already had their general training He wished to bring home to the public the fact that the great voluntary hospitals did not pay probationer nurses adequately for the services they rendered It was true that they were being trained, but they were also working hard all day and all night long to keep the hospital running The whole machinery would stop if the probationer nurse did not work, and for those services she was entitled to payment, and to more adequate payment than she got at present

Prof Robertson's speech has aroused great interest

The Aberdeen Royal Infirmary

The Aberdeen Joint Hospitals Scheme has advanced another stage Last week, at a meeting presided over by the Lord Provost, a motion was carried unanimously authorising the board of directors of the Royal Infirmary to acquire forthwith the part of the Forresterhill site allocated under the scheme and to take all necessary steps towards the erection of a new infirmary upon it The Lord Provost said that they were appealing for the sum of £400,000, and already he had received before the appeal had been issued £212,000. He had gone into the cost of the infirmary part of the scheme with Mr William Kelly, who assured him he would be able to carry out the work at a cost of about £500 per bed, fully equipped, and that would mean that the total cost of the infirmary section would be £257,000

Mr Kelly was the architect who, 36 or 37 years ago, planned the expansions of the present Royal Infirmary He is known as one of the most distinguished of Scottish architects, and it is recognised that the people of Aberdeen reach their objectives without wasteful expenditure, but I cannot help thinking that £500 a bed is a very sanguine estimate in view of experiences elsewhere, even allowing for the fact that the conditions as to site are exceptional

VIENNA

(FROM OUR OWN CORRESPONDENT)

Prof Michael Grossmann

THE medical teaching staff of Vienna University has lost one of its most esteemed members in Prof Michael Grossmann, who has died at the age of 78 Professor for diseases of the throat and nose, and one of the leading specialists in his time, he was at first a surgeon, being assistant to the famous Billroth, and later to Schrotter who in the 'eighties made his clinic famous for the development of laryngology Here Dr Grossmann investigated a large series of pathological conditions and published reports and papers on emphysema, on blood pressure in the lungs, on "nasal asthma," and on the laryngeal nervous system. further, he was active in organising the medical service on railways, for which he wrote a very instructive book, since translated into many European languages He withdrew from public life some eight years ago

The Liver-Fluke in Austria

Liver-rot is not a common disease among the livestock of this country, but is now prevalent in the eastern provinces of the Republic It is caused by the liver-fluke (*Distomum hepaticum* or *Fasciola hepatica*) which is about one inch long, a quarter of an inch broad, and has two "mouths," the second one on the ventral side of the body, and both acting as suction organs The infection of the cattle takes

which does not form part of any other publication and which consists solely of reports of proceedings in courts of law Thus the law reports in the columns of a daily newspaper, however carefully, authoritatively, and unobjectionably prepared and printed, obtain no protection The omission was not a serious matter in the case under discussion, since the Court found the evidence unworthy of belief, but cases may arise where such omissions may be unfair to one of the parties as well as destructive of the value of the *report of the proceedings Admittedly the Act* was imperfectly drafted It contains, for instance, a list of the sole particulars which may be published in reporting a divorce case The names of the parties and witnesses may be reported but not, apparently, the names of judge, counsel, or solicitors, the apparent omission of the judge's name is the more remarkable since his summing-up may be given in full

Over-prescribing under the Insurance Acts

WHERE the fund is limited every reasonable care must be taken to get full value for the money spent This is all that the "checking bureau" means It has worked in Scotland with much success from an early stage in the organisation of National Health Insurance But there has been, from time to time, much heart-burning It is not an agreeable duty for a practitioner to sit in judgment on his fellow practitioner's prescriptions, and I have never heard that any local panel committee enjoyed the job Yet there is no doubt whatever that the general effect of the checking system and the frequent inquiries by the doctors and officials concerned in the administration of medical benefit has been to improve the level of prescribing Probably over-prescribing—which simply means the use of expensive drugs when equally good but cheaper drugs are available—is largely due to defective teaching It must be embarrassing when a professor charged with the scrutiny of prescriptions finds that some of his own favourite prescriptions are among those pilloried as "excessive" by the checking bureau But the explanation is simple Whilst the expense of a drug bears no relation to its therapeutic effect, nevertheless, if "panel" work is an integral part of our domiciliary medical service, the question of expense is very relevant to practice Recently efforts have been made to bring before the medical profession the methods of avoiding expense by selection of drugs, and by careful attention to quantities dispensed, but obviously there is a recurrent irritation among the insurance practitioners It is reported that appeals "against fines amounting to £370 are to be made by eight of 13 Glasgow panel doctors who were surcharged following allegations of over-prescribing" It is sometimes said that insurance patients get one quality of drugs and private patients another, no such distinction is involved in any regulations under the Insurance Acts Whether the machinery for investigating so-called over-prescribing is the best for its purpose is another question The original intention was to enable the medical men themselves to act as checkers of each other's prescribing

Nursing at a Maternity Hospital

Although an amalgamation of the Simpson Memorial with the Royal Infirmary has been arranged, the new accommodation cannot be ready for some seven years Meanwhile the work must be carried on and there is an acute financial difficulty, the main immediate cause of which is a change in the period of training for midwives This has caused a marked falling off in the supply of pupil nurses, and in order to maintain the nursing staff even at a minimum standard it has become necessary to offer free training to pupil nurses who have had their general training Hitherto pupil nurses have paid fees and the giving of free training to the majority of its pupils will mean an actual and immediate loss to the Edinburgh Maternity Hospital of £2000

Prof George Robertson, President of the Royal College of Physicians of Edinburgh, at the recent meeting of the hospital dealt with some fundamental points of hospital administration Everyone, he said, would approve of the directors' decision to give free training to all pupil nurses who had already had their general training. He wished to bring home to the *public the fact that the great voluntary hospitals* did not pay probationer nurses adequately for the services they rendered It was true that they were being trained, but they were also working hard all day and all night long to keep the hospital running The whole machinery would stop if the probationer nurse did not work, and for those services she was entitled to payment, and to more adequate payment, than she got at present

Prof Robertson's speech has aroused great interest

The Aberdeen Royal Infirmary.

The Aberdeen Joint Hospitals Scheme has advanced another stage Last week, at a meeting presided over by the Lord Provost, a motion was carried unanimously authorising the board of directors of the Royal Infirmary to acquire forthwith the part of the Forresterhill site allocated under the scheme, and to take all necessary steps towards the erection of a new infirmary upon it The Lord Provost said that they were appealing for the sum of £400,000, and already he had received before the appeal had been issued £212,000 He had gone into the cost of the infirmary part of the scheme with Mr William Kelly, who assured him he would be able to carry out the work at a cost of about £500 per bed, fully equipped, and that would mean that the total cost of the infirmary section would be £257,000

Mr Kelly was the architect who, 36 or 37 years ago, planned the expansions of the present Royal Infirmary He is known as one of the most distinguished of Scottish architects, and it is recognised that the people of Aberdeen reach their objectives without wasteful expenditure, but I cannot help thinking that £500 a bed is a very sanguine estimate in view of experiences elsewhere, even allowing for the fact that the conditions as to site are exceptional

VIENNA.

(FROM OUR OWN CORRESPONDENT)

Prof Michael Grossmann

THE medical teaching staff of Vienna University has lost one of its most esteemed members in Prof Michael Grossmann, who has died at the age of 78 Professor for diseases of the throat and nose, and one of the leading specialists in his time, he was at first a surgeon, being assistant to the famous Billroth, and later to Schrotter, who in the 'eighties made his clinic famous for the development of laryngology Here Dr Grossmann investigated a large series of pathological conditions and published reports and papers on emphysema, on blood pressure in the lungs, on "nasal asthma," and on the laryngeal nervous system. further, he was active in organising the medical service on railways, for which he wrote a very instructive book, since translated into many European languages He withdrew from public life some eight years ago

The Liver-Fluke in Austria

Liver-rot is not a common disease among the livestock of this country, but is now prevalent in the eastern provinces of the Republic It is caused by the liver-fluke (*Distomum hepaticum* or *Fasciola hepatica*) which is about one inch long, a quarter of an inch broad, and has two "mouths," the second one on the ventral side of the body, and both acting as suction organs The infection of the cattle takes *abortus* (foster father Bang, Denmark) were brought together by Miss Alice Evans, of the Washington laboratory, in 1918 after two decades of separation. Contagious abortion "is so prevalent among cattle that there is little chance for anyone to drink unpasteurised milk for any considerable length of time without ingesting the organism which may cause Malta fever."

Malaria

Malaria has been chiefly tackled in the United States hitherto by drainage and oiling operations, but during 1926 successful experiments were carried out in Virginia by the use of Paris green dusted from an airplane, and it is thought that this method of destroying the malaria mosquito may be applied to large areas at a reasonable cost. Another scheme in progress is the study of the habits of the salt-marsh mosquitoes with a view to reclaiming millions of acres in the South Atlantic and Gulf States at present rendered uninhabitable by hordes of these biting insects which, as far as is known, do not carry specific diseases.

Other Infections

An organised scheme to fill in the gaps in our knowledge as to how tuberculosis is spread, the perfection of scarlet fever antitoxin, the researches into leprosy in Louisiana, Hawaii, and the Philippine Islands, and the investigation of a mild form of typhus fever known as "Brill's disease," endemic in New York and some eastern cities, are other matters dealt with in these articles.

Cancer, goitre, industrial diseases, social diseases, nutritional diseases (especially pellagra, which is quite common in the Southern States), and milk-borne diseases are all being studied. An endeavour is being made to establish a uniform standard for clean milk production throughout all the States.

Child hygiene, rivers pollution, rural sanitation, statistics, and health administration are other matters receiving attention, and the magnitude of this part of the problem is suggested by some figures given—e.g., between 85 and 90 per cent. of the sewage of all the cities in the United States is discharged without treatment into the most convenient stream; 84 per cent. of the rural population are still without the protection afforded by a local full-time health service; 40 per cent. of the 100 largest cities have part-time health officers, and "in nearly 30 per cent. appointment of personnel is still disturbed by political changes in the city administration"; only 79 of the 100 largest cities were in the birth registration area in 1924.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED APRIL 16TH, 1927

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 348 (last week 391); scarlet fever, 1169; diphtheria, 709; enteric fever, 33; *pneumonia*, 993; puerperal fever, 33; puerperal pyrexia, 84; cerebro-spinal fever, 16; acute poliomyelitis, 1; acute *polio-encephalitis*, 3; encephalitis lethargica, 33; continued fever, 1; dysentery, 6; ophthalmia neonatorum, 114. No case of cholera, plague, or typhus fever was notified during the week.

The *cases* of small-pox were notified from the counties of Derby, 6; Durham, 172; Lancaster, 1; Northumberland, 18; Nottingham, 8; Yorks, North Riding, 2; West Riding, 94—all north of the Midlands; and *Monmouth*, 47. Since this return was made up 6 cases have been reported from the County of Middlesex—2 of these from a laundry in Hendon and 4 from a single household in Golders Green.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 3 (1) from enteric fever, 89 (2) from measles, 6 (3) *from scarlet* fever, 65 (10) from whooping-cough, 30 (7) from diphtheria, 39 (9) from diarrhœa and enteritis under two years, and 96 (12) from influenza. The figures in parentheses are those for London itself.

Correspondence.

"Audi alteram partem."

CREAM IN INFANT FEEDING.

To the Editor of THE LANCET.

SIR,—Dr. Donald Paterson, in his article under this title in your issue of April 23rd, refers to diets with a high fat content which are often given to infants. He points out that quite a number of children are unable to manage a high fat-content in their feed, and estimates these as being 1 in 10 of the population. I think he might have gone further than this and referred to the number of children who have a difficulty in the digestion or absorption of fat, even when present in the diet in inadequate amount.

This fat intolerance is sometimes present in the breast-fed child, although it must be remembered that the fat in breast milk is occasionally found to be in excess of the normal, in which case the trouble is really due to too rich a milk. In the case of the artificially fed child the tolerance, or rather the intolerance, of fat is a very common difficulty and the child's digestive system has to be educated to deal with fats by giving them in small, gradually increasing quantities, and working slowly up to the maximum of about 3.5 per cent. in milk mixtures. In addition care should be taken to supply the most valuable kind of fat both from the point of view of its vitamin and nutritional value and also to give these fats in a form in which they can be most readily assimilated.

Dr. Paterson refers to certain synthetic creams, among which he names New Zealand cream, and he makes the observation "that these creams are of great value to the infant apart from their vitamin-content is most debatable." He advocates in place of such synthetic creams the use either of a cod-liver oil emulsion or "a few drops of plain cod-liver oil three times a day immediately before feeds." In my experience, plain cod-liver oil is not so easily tolerated by the child who has a difficulty with fat digestion as an emulsified fat, and for this reason there is a distinct advantage in using a fat emulsion rather than the plain oil. New Zealand cream made under the direction of Sir F. Truby King is especially designed to provide the right kind of fat in the most easily digestible form; it contains 50 per cent. fat of which two-thirds is animal oil including fresh New Zealand butter and cod-liver oil, and one-third vegetable oil, mainly pea-nut; it also contains 40 per cent. sugar, mainly dextrose and a little lactose. The presence of the vegetable oil renders the absorption of the animal oil easier, and of this, I think, there is no doubt. I have used New Zealand cream in such a very large number of cases that I am quite convinced of its value, but I should like to take this opportunity to point out that if this cream is used it is of the utmost importance to give only a sufficient quantity to supply the correct maximum of fat in the diet, and where a child has only been accustomed to a low fat, or in the case of a fat intolerance, it is essential to begin with a small quantity and gradually work up to the full amount required for the 24 hours' supply. I am aware that children have been upset by the incorrect use of this cream and so faults have been unjustly found with it. Recipes for the proper use of it in milk mixtures may be obtained from the Mothercraft Training Society.

I quite agree that it is a common mistake to keep children too long on an exclusive milk diet, and that milk is often given to the older child in too large quantities to the exclusion of the solids which it requires. But does Dr. Paterson really believe that there is quite sufficient fat or cream in "an ordinary diluted cow's milk feed" without any further addition? I should like to know what he means by "an ordinary diluted cow's milk feed." He contradicts himself in his next sentence when he says that every infant, breast or bottle-fed, should be given

Papworth The two are not identical. The French village deals with tuberculous patients of the middle class, its cottages permitting grouping according to occupation or mental and intellectual preference, whereas Papworth provides for patients of rather lower social standing and does much to solve their economic difficulties No French sanatorium for tuberculosis is really comparable to Papworth The Passy Institution is more closely similar to the American cottage sanatorium at Saranac Lake

The Paris Birth-rate

The latest municipal bulletin shows that the number of births in Paris has remained stationary between 1922 and 1926, although the population has considerably increased From 19 to 21 per cent of the infants born in the city are placed with nurses and artificially reared Stillbirths are diminishing here as indeed throughout France, but mortality during the first few months of life remains high, partly because of the transference of infants from mother to nurse

The centenary of Villemin will be celebrated in October He was professor at the Val-de-Grâce Hospital in Paris and was the first to prove that tuberculosis could be conveyed by inoculation, thus laying a foundation for the work of Koch

Yacöel and Boyer recently showed at the Academie de Médecine a case of chronic obliterative arteritis cured by the use of insulin. This condition so often leads to gangrene of the limbs that it is encouraging to hear of numerous successes attending treatment with insulin as given under Prof Vaquez at the Hôpital de la Pitié It is suggested that the disease has its origin, not in microbic infection as has sometimes been believed, but in a trophic disturbance related to abnormal function of the endocrine glands —notably of the pancreas and suprarenals

Dr Paul Marie Léon Regnard, who died recently at the age of 76, was a member of the Academies of Medicine and Agriculture, and had made experimental investigations into the physiology of respiration His many writings included works on epidemic affections of the mind, on life in the sea, on cure by altitude, and on rescue work in mines He was also the author of numerous papers on the anatomy, physiology, and chemistry of agriculture

---

WINDSOR HOSPITAL EXTENSION—The King last week opened a new wing, named after him, of the King Edward VII Hospital at Windsor There are now 50 beds for men, 40 for women, 20 for children, and 15 private wards for patients of small means It will still be impossible to meet the demands of a wide area, and it is therefore intended at an early date to provide a nurses' annexe to release rooms in the main buildings, these rooms will be converted into additional private wards and will make it possible to increase the number of beds for women and children

THE LATE DR. W T BLACKLEDGE—The death took place on April 20th of Dr William Thomas Blackledge, M B E, at his house in Liverpool where he had practised in the Newsham Park district since 1893 He was the second son of the late William Blackledge, of Chorley, and studied at Edinburgh at the University and extra-mural school, graduating in 1893, having previously taken the L R C P & S Edin in 1888 At the University he gained the Junior Mackenzie Bursary in 1885, and the Senior Bursary a year later He also acted as a prosector in the anatomical department under Sir William Turner For over ten years he was assistant surgeon to the Liverpool Police Force and for many years also honorary assistant surgeon to the Liverpool Hospital for Cancer and Skin Diseases An able and enthusiastic Volunteer and Territorial officer he joined the 3rd West Lancashire Brigade, R F A, as surgeon-lieutenant in 1899 In 1911, on the formation of the Territorial Force he took a combatant commission, and in 1913 was transferred to the R A M C, becoming second in command of the 2nd West Lancashire Field Ambulance, with which he was serving at the outbreak of the war During the war he was in charge of military hospitals in Kent, and subsequently commanded the 2/1st West Lancashire Field Ambulance, holding the rank of lieutenant-colonel Later he was president of the Officers' Medical Board in Liverpool

Public Health Services.

A POPULAR SKETCH OF THE AMERICAN PUBLIC HEALTH SERVICES.

TWO recent issues (Feb 4th and 11th, 1927) of the Public Health Reports, issued by the U S Public Health Service, have been largely given up to an account of the many activities of this service written in a popular style which will appeal to a much wider circle of readers than the body of workers for which it is primarily intended The service enlists the aid of medical and other specialists of every description, and its staff includes bacteriologists, zoologists, pharmacologists, and chemists Its functions are mainly research and the setting of a high standard for the inspiration of the various States and local government authorities Every health problem comes within its purview and the description of the investigation of diseases is a tale of high endeavour, not unmixed with martyrdom

Rocky Mountain Spotted Fever

This disease, which attacks the shepherds of Idaho and Montana, had a case-fatality of 80 to 90 per cent in Bitterroot Valley During the investigation a doctor and two assistants working at the Montana laboratory acquired the disease and died within ten days of infection The disease occurs among small rodents and is passed on to other rodents and man by ticks The rodents are not much incommoded by the disease, but are capable of infecting the ticks, which feed on them, for about ten days A vaccine has been prepared from an emulsion of infected ticks and found efficacious for animals In 1924 Dr R. R Spencer took the first dose administered to a human being. Subsequent results indicate that the vaccine is an effective protection to the shepherds who have been vaccinated Among the laboratory workers, before the vaccine was used, there were five infections, all fatal Since the use of the vaccination there have only been four very mild cases which included a man over 60—the first person of that age to recover after infection with the "Bitterroot" strain

Tularæmia

Tularæmia has been known in Utah and adjacent States since 1910 as "deer-fly fever" It begins with an ulcer and feverish symptoms resembling typhoid fever and is apt to cause long disablement of the farmers in the busiest time of the summer It may be fatal, although most patients recover Six workers at the main laboratory at Washington and six more at the Montana laboratory contracted the disease but fortunately all 12 recovered. In 1910 Dr. G W McCoy, of the service, discovered a "plague-like disease of rodents" among the ground squirrels of Tulare County, California This has now been identified with the Utah disease, which is found to be transmitted to man from wild rabbits by flies and ticks One attack gives immunity and the effort to discover a vaccine is being prosecuted by laboratory workers protected in this manner Infected ticks pass the infection through their eggs to the next generation of ticks An infected rabbit is harmless as food after cooking It is suggested that laboratory workers and persons who dress rabbits can protect themselves by wearing rubber gloves Tularæmia has now been recognised in 28 of the States and identified as a disease known for several years in Japan as "Ohara's disease"

Undulant Fever

Malta fever was unknown in the United States until 1905 In 1922 an outbreak of 35 cases in Arizona was traced to goat's milk and in the same year a case in Johns Hopkins Hospital was traced to cow's milk It reads like a romance how the twins *Micrococcus melitensis* (foster father Bruce, Britain) and *Bacillus*

THE RESULT OF AN APPEAL

To the Editor of THE LANCET.

SIR,—My appeal on behalf of a doctor, published in your issue of Dec 4th last, brought in a sum of £114 19*s* 6*d* This is additional to the subscription with which the list was opened Will you and the 42 subscribers please accept my thanks

I am Sir. yours faithfully

Harley-street, W , April 23rd, 1927 HILDRED CARLILL

TESTS FOR DRUNKENNESS.

To the Editor of THE LANCET

SIR,—May I trespass further on your space to make a few observations on Sir William Willcox's letter In the first place I should like to ask for the source of the evidence which proved conclusively to the Committee "that in the performance of complex occupational acts such as the driving of a motor-car an experienced driver might be little affected by relatively large amounts of alcohol since his long experience of driving has caused his control of the car to become almost automatic" More particularly I wish to know why the Committee conclude that the judgment of the alcoholic is little impaired, for this matters just as much as having complete control of the levers of the car A friend of mine accustomed to alcohol in a concentrated form (he has got to the stage when he prefers his whisky neat) tersely and candidly states the difficulty when he says that he gets home more quickly in his car after a few whiskies at his club than when the drinks are omitted till he gets home Then as to Sir William Willcox's observations on the legal objections to the test—I have never advocated taking blood samples, in fact, in the paper I stated that there are obvious objections to the direct method of obtaining the blood concentrations by taking blood samples, &c If the accused person is unwilling to pass a urine sample I think this should be used in evidence against him.

It is refreshing to learn that Sir William Willcox admits the legal value of the chemical proof of absence of alcohol from the urine of a person arrested for drunkenness But why restrict the value to a negative result only? Even if it be not admitted that there is a correlation between concentration of alcohol in the urine and toxic symptoms produced (I think that those who will actually test this out for themselves will agree with me however, that these factors are related) surely it will be of service to the presiding magistrates to be able to state from a quantitative analysis of the urine that the accused must have taken at least so much alcohol? A case in point came to my notice some months ago; a motorist, after zigzagging on the wrong side of the road, grazing a tram-car and knocking a cyclist down then took a tram standard head on, with the result that the impact flung him violently against the steering wheel and he fractured some ribs The injury caused a delay of some weeks in the trial—he was arrested for being drunk in charge of a motor-car. The police surgeon who saw him three-quarters of an hour after the accident considered him not drunk at that time His urine was sent me for analysis It contained 268 mg alcohol per 100 c cm This man must have drunk at least the equivalent of the alcohol in six large whiskies (i e 7½ oz whisky 30 U P) to produce this concentration and yet the accused on oath stated he had had only one gin to drink which will yield a maximum concentration of alcohol in the urine of not more than 50 mg The man was simply fined for negligent driving!

The last two paragraphs of Sir William Willcox s letter seem to me to be a quibble The Committee (page 54 of this report) considering the tests for establishing the fact that an individual is under the influence of alcohol place first on the list the establishing of the fact as to whether or not the person has recently consumed alcohol The whole of the daily press read the report in the sense I indicated in my letter. But whether the test of smelling alcohol in the breath can or cannot be regarded as an essential test for alcoholic intoxication, I repeat my charge that the test is unsound and utterly unscientific

Sir William Willcox has shown the value of a *positive* quantitative estimation of arsenic in the urine in bringing offenders against society to book May I in conclusion appeal to him as Advisor to the Home Office to give the urine estimation a fair trial with all the material that is available in the Metropolitan area? I shall be very glad to pass on my apparatus for this purpose as alas! I have no time now for further investigation along these lines

I am, Sir yours faithfully,

Croydon, April 26th, 1927. H. W SOUTHGATE

COMPENSATION FOR A DAMAGED HAND.

To the Editor of THE LANCET

SIR,—A recent case was heard at the Shoreditch County Court arising out of an accident in which a youth lost the last joint of his right middle finger. £50 was paid into court by way of compensation, but the claimant through his mother claimed £100 Judge Cluer, in rejecting the application of the employer. remarked to the mother that "if you had lost the top of the right middle finger you would have wanted £200 and so would I" The Workmen's Compensation Act has been in force just on 20 years and it still remains without a schedule of fixed amounts for definite injuries Assessments are still arrived at by a more or less rule of thumb We have the schedule of the Ministry of Pensions with which a large number of medical men have become conversant, but it is of no practical use in dealing with claims under the Workmen's Compensation Act. Under this schedule the right middle finger is assessed at £40 whilst two of its joints are worth £30 and one joint £25. Loss of the right middle finger, together with either the index- or ring-finger entitles one to a life pension of 20 per cent which at present rates means 8s. a week

I am, Sir, yours faithfully.

Old Broad-street, E C , April 25th J. J SCANLAN

LOOKING BACK.

To the Editor of THE LANCET

SIR,—I enclose a local paper; a paragraph on p 3, col. 3, has led me to write.

My father, who died in 1888, took his L.R.C S. in 1828 when 19 years of age, there being no restriction as to age then I took the same qualification in 1867. just after completing my twenty-first year: so this is a period of 99 years of practice conducted by father and son.

Looking back many things strike me, noticeably the great decrease in the rural population of this district, the very small birth-rate (10 1 instead of 30), the great diminution of infectious disease treated at home, and the increase in the number of doctors Once upon a time the nearest hospital was 17 miles distant, and there were little or no facilities in the way of nursing for the public Practices were not sold and there were no locum tenents, and an indoor assistant was considered well off with £40 a year.

Every practitioner dressed in a surtout and a tall silk hat. He visited his patients within the town postal delivery by walking and the country patients on the back of a horse or in a gig or by a combination of the local railway (when it came). and walking. In my opinion a good saddle horse was the best way of conducting country work. On more than one occasion I have ridden 50 miles. returning home within eight hours I learned cycling when 50 years of age, thinking to save money, and I have even used a motor-cycle, and now on occasions hire a car.

I am Sir, yours faithfully,

Crieff. April 18th 1927 JAMES GAIRDNER

** The *Strathearn Herald*, which our correspondent forwards announces Dr Gairdner s increase of salary by the Crieff Parish Council, in appreciation of his long service as medical officer of health suitable mention of which is also made on the minutes of the council —ED L cod-liver oil Is it necessary or even advisable to give cod-liver oil to a breast-fed child unless it is proved that the mother's milk is deficient in fat, or that her diet is lacking in animal fat ? Would it not be better even in these cases—which must be rare—to give the cod-liver oil to the mother rather than to the child ?

As to whether fat is needed rather for its vitamin-content than for its food value is a question which we must look to the physiologists to determine, but until we are better informed surely we must believe that it is of value from both these points of view What would be the effect on nutrition and growth of a fat-free diet plus an extract of the fat-soluble vitamins if such an extract could be prepared ?

I am, Sir, yours faithfully

Reginald C Jewesbury

Wimpole street, W , April 25th, 1927

ANTERIOR SUBLUXATION OF THE ATLAS

To the Editor of The Lancet

Sir,—Mr Alwyn Smith and Mr Lambert Rogers seem to me to be entirely right in their criticism of Prof Oppel's interesting case I have assembled a considerable amount of material on this and allied lesions of the upper cervical vertebræ which I hope to have ready for publication shortly It is evident that the dislocation is a sign of some other injury This may seem an obvious statement to make, since dislocations in general are due to violence which has ruptured the ligaments holding the bones together, and usually continued long enough to displace the bones In this particular region immediate recoil into normal position may take place, and dislocation occur later, even intermittently, by means of the forces of gravity or muscular action In the case of the occipito-atlanto-axial component the dislocation is the end-result usually of a fracture of the odontoid process or of rupture of the transverse ligament Prof Oppel correctly remarks that the former—i e , odontoid fracture—is the commoner, much the commoner In his case we may assume that the odontoid has not broken through at the neck. There is, however, another horizontal fracture of the axis (I shall refer to the distinction between horizontal and vertical fractures of the axis in a forthcoming paper) which is more difficult to diagnose, and therefore escapes notice more often even than the more common varieties I may remark in parenthesis that the most potent reason for failure to diagnose them is implicit in a remark of Prof Oppel's " And what surgeon does not know that the history of anterior subluxations of the atlas is one of sudden death caused by trauma ? The number of patients who have not succumbed to such a lesion may be counted on the fingers " With the greatest respect to Prof Oppel, who has done much for the cause of surgery, I must strongly disagree with this statement, which does, however, embody the general impression of our profession towards injuries Medical men feel that any case of their own cannot possibly have an injury involving atlas or axis because the man is still alive ! Hence a number of cases are missed Of course, if a complete luxation occurs death must result, but this is a great rarity. A subluxation, such as Prof Oppel describes, is much the commoner, and even when untreated these do not as a rule become complete luxations unless the cause of the displacement is disease in the bones and ligaments (i e , pathological dislocations).

The second variety of axis fracture to which I commenced to refer is an oblique fracture downwards and forwards through the body of the bone, and this may liberate the odontoid and allow an anterior subluxation to occur In these cases the neck of the odontoid resists fracture, but a considerable fragment of the axis comes away with it The antero-posterior view through the mouth usually fails to reveal a clear fracture line and all that one sees distinctly is that the odontoid is intact Even in the lateral view the fracture may be difficult to make out The presence of a bone fragment in front of the axis suggests that this may have been the pathology of Prof Oppel's case To be sure the fragment may have been displaced downwards at the operation, and may even be adventitious, as it was not seen in the first photograph

I do not think that Prof Oppel is justified in his diagnosis of fracture of the anterior arch of the atlas Judging from the tracing the appearance of the anterior arch is not abnormal I doubt whether a fracture of the anterior atlantal arch will often be diagnosed during life, for it is difficult to see clearly except in profile There is certainly no reason why it should be dangerous Most of the few published " fractures " of the anterior atlantal arch are developmental defects I have commented (*Brit Jour Surg* 1920) in a paper on Atlas Fractures on a very beautiful example published by Sybenga (1919).

I agree with Mr Alwyn Smith and Mr Rogers that laminectomy would be the better operation, perhaps combined with removal of the posterior margin of the foramen magnum, if the patient had pressure signs and the displacement had occurred for so long that one was afraid of manipulation. The ideal operation, however, is unquestionably replacement and fixation, the latter not by means of an Albee graft, as Prof. Oppel tentatively suggests. A successful graft must lie in an osteogenetic medium, and although it might " take " below in the rongeured and split lower cervical spinous processes, I cannot imagine its uniting above to the occipital bone, with its feeble powers of bone formation The alternatives lie between an arthrodesis in the atlanto-axial joints, or slinging the posterior arch of the atlas to the tunnelled spine of the axis by strong fascial grafts or slips from the tendo Achillis –much the easier procedure

I am, Sir, yours faithfully,

Manchester, April 15th, 1927 Geoffrey Jefferson

BROMSULPHALEIN

To the Editor of The Lancet

Sir,—In a recent leading article (The Lancet, Feb 19th, p 400) dealing with liver function tests and their clinical value, reference was made to an article by Dr Ernest Bulmer (*Quart Jour Med*, 1927, xx , 101) upon the bromsulphalein dye test Bulmer was unable to obtain satisfactory results with this test, and in normal individuals he obtained widely divergent results, not at all agreeing with the standards we have set Thus we have found that in normal cases after an intravenous injection of 2 to 5 mg of bromsulphalein the liver is completely able to remove the dye from the blood-within 30 minutes Bulmer, however, in his series of normals, reports retention of the dye in the blood, up to 45 per cent , 30 minutes after its injection The reliability of a test of this nature depends primarily upon a constancy of findings in normal individuals, and in view of the fact that in a large series of investigations we have never encountered a single exception to our " normal " standards, Bulmer's work deserves further criticism.

The explanation of Bulmer's results apparently lies in the drug which he used Bromsulphalein was synthesised in the laboratories of Hynson, Westcott, and Dunning, Baltimore, Md , by Dr E C White Its preparation is difficult and the technical details of its manufacture have not yet been published The dye employed by Bulmer was obtained from a local chemist, and Dr White states that it would be practically impossible to make bromsulphalein from the information at present available Bulmer was probably not using bromsulphalein, and it seems advisable to correct the erroneous impression of this test which his work conveys Numerous workers have demonstrated the superiority of the dye test (based upon its removal from the blood stream) over carbohydrate tolerance tests, and in chronic liver disease this test is often the only method which will reveal impaired function

I am, Sir, yours faithfully,

THE TOTAL ECLIPSE OF JUNE 29th, 1927

PROTECTION OF THE EYES

By ARNOLD LAWSON, K B E , F R C S Eng ,
SENIOR OPHTHALMIC SURGEON, MIDDLESEX HOSPITAL,
AND
ARTHUR L WHITEHEAD, F R C S Eng ,
CONSULTING OPHTHALMIC SURGEON, GENERAL INFIRMARY, LEEDS

The forthcoming eclipse of the sun brings up again the question of protecting the public from the serious risk to the eyesight which must accompany any attempt to observe the sun's disc without an efficient light filter before the eyes On previous occasions a general warning has been issued through the press, advising the wearing of dark-tinted glasses or the use of a piece of glass smoked in a lamp or candle flame The matter, however, has never received the attention it deserves, and, beyond formulating the desirability of protection, the detail as to tint, density, and elimination of particular portions of the spectrum has been left practically untouched

On this account we have been giving the matter a very careful examination, the result of which is that it will now be possible for everybody to obtain at a trifling cost a screen through which the eclipse can be observed throughout all its phases without dazzling, and with perfect comfort and safety to the eyes The question was not so easy or straightforward as might appear at first sight For the sake of clearness it is as well to enumerate the essential points which such a screen must possess

(a) In order to avoid all risk of "eclipse blindness" it is imperative to employ a screen which will cut out the powerful ultra-violet rays of the sun's beam These rays constitute a considerable portion of the sun's radiant energy Being invisible, they are useless for vision, and when intense, as they are in direct sunlight, they are very irritant to the eye

(b) A second essential is to decrease the general luminosity sufficiently to remove the insupportable glare from the sun's orb

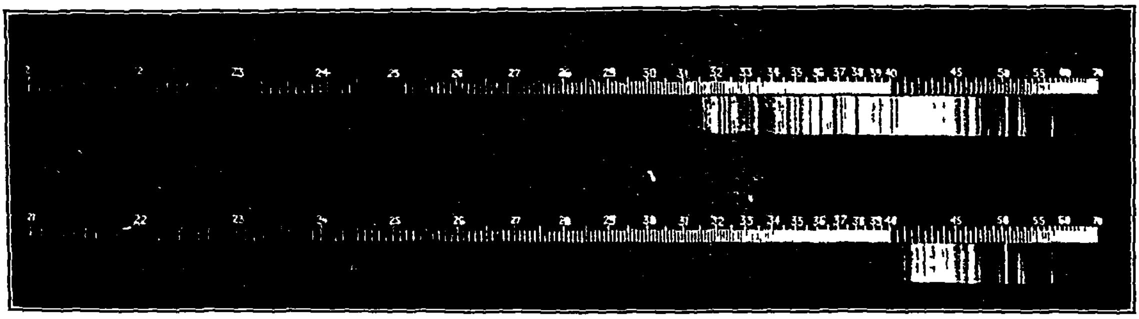
(c) These two previous desiderata must be so arranged that the observer may be able, not only to see the outline of the sun as it varies with the progress of the eclipse, but may also be enabled to view the less conspicuous phases of the eclipse in comfort

(d) The public must be made to understand that neither simple smoked glass nor fogged photographic film are safe screens even when well prepared, for in neither case are the irritant ultra-violet rays absorbed These screens do no more than reduce the intensity of the beams

(e) The screen must be put on the market at such a low cost that its purchase will come easily within the means of the working classes

We at first turned our minds to existing kinds of glass on the market with the hope of finding what we wanted Crookes's glass fulfilled the essential of cutting out ultra-violet radiation, but in other respects even the darkest shade obtainable was far from satisfactory Peacock blue seemed to be much the best glass, because it is not only as efficient as Crookes's glass with regard to absorption of ultra-violet rays, but it also entirely cuts out the red end of the spectrum, and thereby imparts a peculiar sense of coolness and comfort However, it fails again in allowing too much of the luminous radiation to come through, and further it interferes seriously with the colour scheme and would altogether mask the natural coloration of the sky and eclipsed sun. Moreover, when the essential question of cost came to be considered, both Crookes's and peacock blue glass, apart from the question of fitness for the purpose in hand, were much too expensive for production at the low cost which, as already pointed out, is absolutely essential if the mass of the general public are to be persuaded to purchase the screen.

At this juncture we approached Mr Theodore Hamblin, of the well-known firm of opticians, 15, Wigmore-street, London, W 1, who suggested calling in the advice of Dr Judd Lewis These two have worked in collaboration with the result that Dr Lewis has produced exactly what is wanted, which Mr Hamblin is prepared to put on the market at the essential low cost Briefly, Dr Lewis has evolved the idea of utilising photographic film, which is first fogged by exposure to light so as to produce a certain density, and then treated by a special method, as a result of which all the spectrum of wave-length shorter than 4000 Angstrom units is cut off (see figure) By this means a medium is obtained which reduces the luminosity of the sun to a safety point and also entirely disposes of all danger from ultra-violet radiation Simple fogging would not alter the character of the spectrum, but only reduce its intensity, which, as already pointed out, is not a sufficient safeguard if a person gazes for any length of time at the sun's orb Further, this treatment does not alter the colour of the film so that the sky and eclipsed sun are seen in their natural colour This prepared film has been registered under the name of "Eclipsia" and Mr. Hamblin has arranged to put it on the market in two forms The cheaper form will be provided in the character of a mask and sold at a shilling, which will bring it within reach of every purse, and in addition there will be a rather more elaborately contrived arrangement at a slightly increased cost for those who desire it This latter type will contain three screens of different densities—one, very dense, for viewing the sun when it is but little eclipsed; a medium density for observation when the eclipse is well advanced , and one which is nearly clear for observation when the eclipse is nearly total



Spectrograph by Dr Judd Lewis The upper figure shows the spectrum of untreated and the lower that of treated photographic film The completeness of the cut-out of the ultra-violet radiation in the lower figure is well shown

Our personal connexion with the matter is now at an end We hope that we have secured the safety of the public by initiating this investigation, and we heartily congratulate Dr Lewis on his scientific acumen and Messrs Hamblin on the interest they have displayed and the business-like manner in which they have realised and tackled the proposition Messrs Hamblin have control of the manufacture of "Eclipsia" and all inquiries with regard to this matter must be addressed to the firm We can only trust that through the medium of

Obituary.

ANDREW STANFORD MORTON, M B, F R C S Edin, F R C S Eng

Mr A S Morton, who died in retirement at Clifton on April 11th, will long be remembered by the profession at large for his invention of an ophthalmoscope which is in general use at the present time and which goes by his name But his reputation amongst those who worked with him depends rather upon his competence as a clinician and operator than on any special device or achievement

Graduating at Edinburgh in 1874, Mr Morton went south to University College, London, and later studied at Paris He became a Fellow of the Royal College of Surgeons of Edinburgh in 1877, before which time he had started ophthalmological work as house surgeon to the Royal London Ophthalmic Hospital (Moorfields) His first staff appointment was to the Royal South London Ophthalmic Hospital at Southwark, but he continued to attend Moorfields as clinical assistant, and a few years after taking the F R C S Eng in 1888 was appointed assistant surgeon there Later he became ophthalmic surgeon to the Royal Northern Hospital At Moorfields Morton's work and teaching was much appreciated To the older generation of students he was known as a thoroughly sound and dexterous operator, and his classes, at which he demonstrated (on pigs' eyes) the chief ophthalmic operations, were always popular The knowledge which he had gained under such excellent masters as Mr George Critchett and Sir William Bowman, whom he served when house surgeon at Moorfields, was well utilised In diseases of the eye, however, operative skill is not solely a matter of education, it depends largely on innate capacity, and with this capacity Mr Morton was richly endowed He was a tall, stoutly built man, but had small strong hands with beautifully tapering fingers, and the masterly way in which he wielded a Graefe's knife impressed the onlookers from all parts of the world who congregated at Moorfields Curiously enough, though his dexterity was great and his judgment sound, he never seemed to realise the advantages of modern aseptic methods and preferred always to operate, as his predecessors had done, in his everyday coat An ardent refractionist at the time when retinoscopy was first introduced, Mr Morton seized the moment to publish a short book on the corrections of errors of refraction which gave a clear account of the subject and passed through several editions He was a good draughtsman with an excellent eye for colour, and he made use of these gifts in depicting, with much patience and accuracy, diseases of the fundus of the eye as seen with the ophthalmoscope The early volumes of the Transactions of the Ophthalmological Society were much enriched by the reproduction of these paintings, the originals of which are preserved in the museum at Moorfields Hospital

Mr Morton was at one time vice-president of the Ophthalmological Society of the United Kingdom, and received for professional services the rank of Chevalier of the Crown of Italy He retired in 1920 and was 79 years of age at the time of his death

HARRY MATTHEWS, B Chir Camb

The death, at the early age of 51, of Dr Harry Matthews, of Whitehall-court, has come as a shock to a large circle of friends and patients Since August of last year his health had been failing but he continued his work cheerfully until about two months before his death Born in 1875 at Sporle, Norfolk, the youngest son of the late Thomas Matthews, of Sporle, he was educated at Grantham Grammar School (the school of Isaac Newton), St John's College, Cambridge, and St Mary's Hospital He graduated in Arts in 1897 and took the B Chir in 1900, and at Cambridge was prominent both on the football field and the river After filling house offices at his hospital, where he was house surgeon to the late Mr Edmund Owen, he joined the late Dr Boyter Johnson in practice at Whitehall-court.

During the war he obtained a temporary commission early in 1917 and was attached to the 51st Field Ambulance (17th Division), then under the command of Lieut -Colonel E L Gowlland, D S O For some months he was on duty in the trenches and in the advanced dressings stations near Gavrelle West of Monchy To quote the words of Colonel Gowlland "His unfailing cheerfulness, quiet courage, and above all his kindness and sympathy with the men under him and with his patients made him a most valuable officer, and the Field Ambulance was the poorer when he was transferred to the Headquarters' Staff of the Vth Army Corps" At the Corps' Headquarters Matthews had medical charge of the personnel of the staff, and in addition attracted to himself a large clientèle among the peasants in the various villages in which the staff was billeted. With many of these humble patients he corresponded for some time after the war

Harry Matthews was a good example of a type of general practitioner found at its best development in this country One of his old chiefs writes of him "He had a real clinical instinct born of years of patient and conscientious observation, he kept himself abreast of the developments of modern medicine, and possessed that instinct of service which led him to give his all ungrudgingly to those who placed their confidence in him To Harry Matthews all class distinctions vanished where a patient was concerned." And this was exemplified by the large and varied congregation which assembled at the memorial service held to his memory in St Martin's Church, W C He was buried at Newton-by-Castleacre, Norfolk

The Services.

ROYAL NAVAL MEDICAL SERVICE

Surg -Comdr H B Hill to *President*, Surg Lt -Comdr K A I Mackenzie to *Victory*, Surg -Lt M Brown to *Britannia* for R N Sick Quarters, Dartmouth

ROYAL ARMY MEDICAL CORPS

Maj J R P Allin to be Temp Capt. and temporarily relinquishes the rank of Maj

Capts to be Majs R B Myles, G W Rose, J T. McConkey (Prov), and R McKinlay

To be Temp Lts D J Allan and G M Cooper

ARMY RESERVE OF OFFICERS

Capt G T Baker relinquishes his commn and retains the rank of Capt

Capt R M Le H Cooper, having attained the age limit of liability to recall, ceases to belong to the Res of Off

TERRITORIAL ARMY

Lt -Col T A Hindmarsh, from Active List, to be Lt Col. Supernumerary for Service with O T C—Maj H H Woollard resigns his commn

ROYAL AIR FORCE

The undermentioned Flight Lts are promoted to the rank of Squadron Leader. T R S Thompson and R S Topham

INDIAN MEDICAL SERVICE

The King has approved the retirement of Lt.-Cols J G P. Murray and R M Carter

Capts Anant Yashwant Dabholkar, Ram Nath Khosla, and Ratenshaw Nariman Kapadia, S A McSwiney, and Huggahalli Sundra Rajan to be Majs

Capt Srish Chandra Sarkar (permitted to retain the rank of Capt), and Lt Jodh Singh Guruwara relinquish their temp commns

Kulwant Rai to be Lt.

Dr Arthur Young has been appointed pathologist to the Institute of Medical Research, Kuala Lumpur, Federated Malay States

Royal Medico-Psychological Association —The next quarterly general meeting of this association will be held on Thursday, May 19th, at the house of the British Medical Association, Tavistock-square, London, W C 1, under the Presidency of Lieut -Colonel J R Lord At 3 30 P.M Lieut.-Colonel Edwin Goodall will deliver the Eighth Maudsley Lecture, in which he will deal with Some of the Work Done to Elucidate the Pathology of Disease Falling to be Considered Under the Rubric " Insanity "

Dental Clinic at the Royal Free Hospital Mr George Eastman, the head of the Kodak Company, has given £300,000 for the establishment of a dental, tonsil and adenoid clinic which is to be associated with and adjoin the Royal Free Hospital Ten years ago Mr Eastman provided a similar clinic, at Rochester in the State of New York, which has done such good work that he desires to establish one in Europe on the same lines and regards London as the best centre. It is hoped that the building will be completed within the next two years Dr H J Burkhart, the American dentist who is representing Mr Eastman, states that there will probably be 50 chairs in the main infirmary and 7 in the orthodontic department A condition of the gift is that money should be provided for maintenance and operating expenses

Royal Northern Hospital *Post-Graduate Instruction* —Two separate courses are offered at this hospital The first is open to all practitioners free of charge and its object is to present up-to-date information in such a form that it can readily be applied in practice It consists of a weekly lecture on Tuesdays at 3 15 P M , followed by tea, and the series held since January, which has been well attended, will go on until the end of June , a programme shows the scope and variety of the lectures Three times a year—in February, May, and October—intensive courses are held They last for one week, during which time the entire hospital is thrown open to practitioners two lectures or lecture demonstrations being given every afternoon The next intensive course will begin on Monday, May 23rd The other instruction given at the hospital is for the benefit of candidates for the M D or M R.C P examinations The course deals with recent advances in medicine with important points in biochemistry, bacteriology, and general pathology, and with medical anatomy. It is held three times a year—the next being in the second half of June—and lasts from two to three weeks a fee of 5 guineas is charged Further particulars may be had on application to Dr E G B Calvert, Dean of the hospital

Fellowship of Medicine and Post-Graduate Medical Association —Mr C B Goulden will give a demonstration at the Royal London Ophthalmic Hospital on Tuesday, May 3rd, at 1 P M. This demonstration is free to members of the medical profession. Several special courses have been arranged for May The staff of the All Saints' Hospital will give a series of clinical and cystoscopic demonstrations from May 2nd to 28th and on every Wednesday during the four weeks a lecture will be delivered at 2 P M. The Maudsley Hospital will hold between the same dates an afternoon course in psychological medicine; demonstrations on the pathology of mental diseases, clinical psychiatry, and the psychoneuroses are some of the many subjects to be dealt with Another course, beginning on May 4th and continuing for four weeks, is that provided by the London Lock Hospital , it comprises clinical teaching in the out-patient department and a series of formal lectures dealing with the various phases of venereal disease On successive Wednesdays from May 4th to 25th, Prof Louise McIlroy will give lecture-demonstrations at the Royal Free Hospital on antenatal diagnosis and treatment An intensive course will be given at the Central London Throat, Nose and Ear Hospital, from May 9th to 28th , early application is desirable as the operative course has a limited entry From May 9th to July 15th the National Hospital, Queen square, will hold a course on neurology, comprising clinical lectures and demonstrations, teaching in the out-patient department and pathological demonstrations and lectures , there will also be a course in anatomy and physiology and one in methods of examination Two other courses beginning on May 16th, and continuing for two weeks, are those at the Infants Hospital and the Hampstead General Hospital The former will be of special interest to those engaged in infant welfare work , the latter is primarily for the general practitioner Copies of all syllabuses, of the general course programme, and of the *Post Graduate Medical Journal* are obtainable from the Secretary of the Fellowship, at 1, Wimpole-street, London, W 1

People's League of Health —The League has arranged four lectures on Sunlight and Health, to be given at the rooms of the Medical Society of London 11, Chandos-street, Cavendish-square, W 1, on May 12th, at 6 P M., and at the same hour on the following Thursdays Among the lecturers will be Dr Leonard Hill, F R S , and Dr P C Varrier-Jones Tickets and further information may be had from Miss Olga Nethersole, R R C , at 12, Stratford-place W 1.

Chelsea Hospital for Women.—The annual report states that the past year has been the first to show the working capacity of the new building The number of in-patients rose from 775 in 1924 to 1437 in 1926 The major operations rose from 495 to 800, and the minor operations from 290 to 609 During the year 226 patients were received into the " paying floor " of 18 beds which may be looked upon as self-supporting

Montreal Typhoid Epidemic —The origin of this epidemic, which began on March 4th and has resulted in 2435 cases, with 182 deaths, has, it is believed, been traced to a man, a typhoid " carrier " of 20 years' standing, who obtained employment in a city dairy in ignorance of his condition.

The late Dr Caroline Matthews —At the age of 49 Dr Caroline Matthews has died at Sydenham from influenzal pneumonia The daughter of the late Mr John Twigge, of Liverpool, she received her medical education at the University of Edinburgh where she graduated in 1903 Both during the Messina earthquake of 1908 and the epidemic of small-pox at Cinquefrondi in Calabria in 1909 she saw service as surgeon with the Italian forces, and in 1911 she received King Victor Emanuel's commemoration medal and the Italian Red Cross Medal During the Balkan War of 1912–13 she was attached as surgeon to the Montenegrin army, receiving the Order of Danilo , she also acted as war correspondent to the *Sphere* On the outbreak of the late war she hurried back to the Balkans at her own expense, to offer her services to the Serbs The conditions were very bad and when the Serbs evacuated Uzsitsi in October, 1915, Dr Matthews decided to remain behind in charge of the military hospital to which she was surgeon She is said to have refused to undertake some of the medical work required of her by the Austro-German command, and she was taken to Belgrade as a prisoner of war on a charge of espionage. These experiences undermined her health Dr Matthews was the author of various newspaper articles besides a number of books describing her adventures

Deputation on Irish Medical Affairs —A deputation from the Irish Medical Committee, consisting of Dr R J Rowlette Dr A McBride, Dr J B McClancy, Dr J P Shanley, Dr M O'Brien, Dr T Hennessy, and Mr C H Gick recently waited on the Department of Local Government and Public Health in connexion with the following matters (1) transfer of medical officers under the Local Authorities (Officers and Employees) Act, 1926 ; (2) private patients in county and district hospitals , (3) remuneration of Registrars of Births Deaths and Marriages The deputation was received on behalf of the Minister by Mr E P McCarron, secretary, and Dr E F. Stephenson, chief medical adviser to the department With regard to the transfer of medical officers, the deputation urged that the Minister should refuse to sanction any transfer made as promotion unless the officer transferred was entitled to promotion on the grounds of merit or long service in accordance with the intention of Section 5 of the Act. Mr McCarron and Dr Stephenson agreed that the section quoted had for its object the promotion of existing officers on the lines stated by the deputation and undertook to convey its views to the Minister With regard to the admission of private patients to county hospitals, the deputation stated that whilst it was satisfied with the draft regulations forwarded by the department to the county health boards for adoption, these bodies did not show any desire to put them in force, and thus enable the doctors attached to the hospitals to arrange with private patients for payment for their medical attendance The deputation was informed that the department would use its influence, in the first instance to have the draft regulations adopted by the health boards, and in the event of their refusal it would consider further representations from the profession In connexion with the increased remuneration for registrars, the deputation was invited to prepare a memorandum stating the position of these officials Mr McCarron and Dr Stephenson agreed that the fees paid at present for this work were inadequate More than 90 per cent. of the registrars in Ireland are dispensary doctors and the registration areas correspond to their dispensary districts

THE LANCET the general public may be again cautioned and informed of the means that lies at hand of enjoying with perfect comfort and safety all the wonderful phenomena of the eclipse

ST THOMAS'S HOUSE.

A RESIDENTIAL CLUB FOR MEDICAL STUDENTS

A RESIDENTIAL club for the students at St Thomas's Hospital, adjoining the grounds of Lambeth Palace, was opened on Tuesday morning last by the Archbishop of Canterbury The fine building of seven storeys contains over 70 bedrooms, as well as all the accommodation necessary for the social life of the students The mantel-piece in the common-room forms the war memorial erected by past and present students of St Thomas's to the memory of their fallen brethren and was unveiled by the Archbishop at the close of the opening ceremony.

The *Archbishop*, with whom was Mrs Davidson, was received by Sir Arthur Stanley (Treasurer of the Hospital), Sir George Makins (Chairman of the War Memorial Committee), and Dr L B Maxwell (the Warden of the House) The company assembled in the common-room when Sir Arthur Stanley explained the need which had been felt for some time for proper club accommodation for the students, who had surrendered their previous none too good premises which were now being used as laboratories in response to the growing demands of medical education Not only, he said had these premises to be replaced, but quarters could no longer be found in the Hospital for the large resident staff, and the erection of the St Thomas's House was decided upon The scheme became immediately possible by the generosity of Lord Riddell who lent them at once the sum of £30,000 at very low interest, a similar sum, the governors thought, was within their capacity to raise, the House costing some £60,000 Sir Arthur Stanley thought the governors and staff of the Hospital could congratulate themselves upon St Thomas's House as a practical demonstration that their Hospital, though even its re-endowment dated from 1215, was still in the van

Lord Riddell and Sir Cuthbert Wallace, the Dean of the medical school, spoke briefly of the value from all points of view of the possession by the Hospital of such a social centre

The *Archbishop* expressed his great pleasure at being connected with the ceremony, the association was natural as for centuries before the present hospital arose on the south bank of the Thames the Archbishops of Canterbury had been located there, he thought to the benefit of their neighbours apart from anything religious or ecclesiastical

The Lord Mayor of London thanked the Archbishop in the name of the City of London, and Sir George Newman spoke of the value of social amenities to a university medical school The Archbishop then unveiled the memorial and received through Mr. C A R Nitch a cheque for £700, money contributed by the honorary staff of the Hospital, for the furnishing of the club room

A short service having been conducted by the Rev. R B Cornish the proceedings closed with the singing of the National Anthem

---

MUNICIPAL DENTAL HOSPITAL — Mr John Wheatley, M P, recently opened a municipal dental hospital which has been started at Shoreditch, under the powers granted to borough councils to establish hospitals Dental work will be done for the maternity and child welfare centre and treatment will also be given at moderate fees to persons residing or working in the borough The staff includes an anæsthetist and a dentist who is also a registered medical practitioner It is intended that the new institution shall give dental care to people who would not otherwise get it, and propaganda will be undertaken to impress on the inhabitants of Shoreditch the need for looking after their teeth

Medical News.

SOCIETY OF APOTHECARIES OF LONDON —At recent examinations the following candidates passed in the undermentioned subjects —

Surgery —L G Apps, P Brookes, and W H Collins London Hospital, A. F J D'Arcy, St Mary's Hospital, W Howard, Liverpool S B S Smith, St Bartholomew's Hospital, and L Wasef, Manchester

Medicine —D K Reynolds, King's College Hospital, and S K Rigg, Bristol

Forensic Medicine —J Bramall, Leeds, C M Brock, Durham J A Fernandez, St Bartholomew's Hospital, W D Neill, London Hospital, and D K Reynolds, King's College Hospital

Midwifery —P Brookes, London Hospital, R P Charles, King's College and Charing Cross Hospital, W Howard, Liverpool, H S Marks, Guy's Hospital, B Rosenan Middlesex Hospital, S B S Smith, St Bartholomew's Hospital, and M A Yousef, Liverpool

The Society's diploma of licentiate was granted to Mr L G Apps

UNIVERSITY OF GLASGOW —On April 23rd the following degrees were conferred .—

M D

†R L Mackay, *D M Lindsay, *James Lindsay, Grace M Lintock, and P O Moffat

CH.M

†J R Learmonth

B Sc

In Public Health —R L Leask

M B, CH B

With Honours —James Richard and W F Greer

With Commendation —F T Land, Albert Sharman, C A Robinson, Jeannie M'C Robertson, and Hugh Black

Ordinary Degree —Waradea Abdurahman, Margaret K M Alexander, Archibald Blair, G F Cables, Angus Campbell John Campbell, Margaret C Campbell, Colomba C Caraldi, Hugh Dickie, Joseph Downes D J Ferguson J S Ferguson, J A Fleming, H W O Frew, J P Galloway, Thomas Gibson, Mary L Gilchrist, Marjorie Gillespie, W H Graham, B M Hegarty, James Hepburn, James Hill H Y Lavelle, J L M'Colm, E C Macdonald, Isabel M Macdonald, C J M'Ghee, I S M'Gregor, A A M'Millan D R M Pherson, Alexander Matchett, J F Milne, R A Neill, R L Paterson Annie B Price, J A Reid, J F Russell, F F Schorn Sydney Sharman, J S Sharpe, J B Simpson, Nathan Smith, Peter Spence, A M'D Steel J R Sutherland Anne I Symington, A C Thomson, Donella A F Watson, William Watson, and Edward Yoddes

* With commendation for thesis
† With high commendation for thesis

UNIVERSITY OF LONDON *London Hospital Medical College* —The Schorstein Memorial Lecture will be delivered by Prof Knud Faber, of the University of Copenhagen at 4 15 P M, on Thursday, May 19th, in the Anatomical Theatre of the College His subject will be Gastritis, Its Relation to Achylia and Ulcer Members of the profession are invited to attend

UNIVERSITY OF BIRMINGHAM *William Withering Memorial Lectureship* —A course of ten lectures on Organic Inheritance in Man is being given by Dr F A E Crew at the Medical School, Edmund-street, Birmingham The first two lectures were delivered on April 27th and 28th. Subsequent lectures will be given at 4 P.M on May 4th, 5th, 12th, 19th, 25th, 26th, and June 1st and 2nd

INDIAN MEDICAL SERVICE DINNER —The annual dinner of the Indian Medical Service will be held at the Trocadero Restaurant on Wednesday, June 15th, at 7 15 for 7 30 P.M. Major-General R W. S Lyons has been invited to take the chair Tickets and all particulars may be obtained from the joint hon secretary, Colonel J J Pratt, I M S (ret), 18, Nevern Mansions, Warwick road, London, S W 5

NATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS —The thirteenth annual conference of this Association will be held at the House of the British Medical Association, Tavistock-square, London, W C 1, on June 30th and July 1st and 2nd It will be opened on Thursday, June 30th, at 10 30 A.M. by Mr Neville Chamberlain, the Minister of Health, and the main subject of discussion will be the present lines of attack on tuberculosis and their relative value Amongst those who will take part are Sir John Robertson Prof H R Kenwood, and Prof Edgar L Collis Visits will be paid to various institutions and housing schemes The conference will be open to all persons interested in tuberculosis on payment of the fee of one guinea

Dr Arthur Young has been appointed pathologist to the Institute of Medical Research, Kuala Lumpur, Federated Malay States

Royal Medico-Psychological Association —The next quarterly general meeting of this association will be held on Thursday, May 19th, at the house of the British Medical Association, Tavistock-square, London, W C 1, under the Presidency of Lieut -Colonel J R Lord At 3 30 P.M Lieut -Colonel Edwin Goodall will deliver the Eighth Maudsley Lecture, in which he will deal with Some of the Work Done to Elucidate the Pathology of Disease Falling to be Considered Under the Rubric " Insanity "

Dental Clinic at the Royal Free Hospital. Mr George Eastman, the head of the Kodak Company, has given £300,000 for the establishment of a dental, tonsil, and adenoid clinic which is to be associated with and adjoin the Royal Free Hospital Ten years ago Mr Eastman provided a similar clinic, at Rochester in the State of New York, which has done such good work that he desires to establish one in Europe on the same lines and regards London as the best centre It is hoped that the building will be completed within the next two years Dr H J Burkhart, the American dentist who is representing Mr Eastman, states that there will probably be 50 chairs in the main infirmary and 7 in the orthodontic department A condition of the gift is that money should be provided for maintenance and operating expenses

Chelsea Hospital for Women —The annual report states that the past year has been the first to show the working capacity of the new building The number of in-patients rose from 775 in 1924 to 1437 in 1926 The major operations rose from 495 to 800, and the minor operations from 290 to 609 During the year 226 patients were received into the " paying floor " of 18 beds which may be looked upon as self-supporting

Montreal Typhoid Epidemic —The origin of this epidemic, which began on March 4th and has resulted in 2435 cases, with 182 deaths, has, it is believed, been traced to a man, a typhoid " carrier " of 20 years' standing, who obtained employment in a city dairy in ignorance of his condition

The late Dr Caroline Matthews —At the age of 49 Dr Caroline Matthews has died at Sydenham from influenzal pneumonia The daughter of the late Mr John Twigge, of Liverpool, she received her medical education at the University of Edinburgh where she graduated in 1903 Both during the Messina earthquake of 1908 and the epidemic of small-pox at Cinquefrondi in Calabria in 1909 she saw service as surgeon with the Italian forces, and in 1911 she received King Victor Emanuel's commemoration medal and the Italian Red Cross Medal During the Balkan War of 1912–13 she was attached as surgeon to the Montenegrin army, receiving the Order of Danilo , she also acted as war correspondent to the *Sphere* On the outbreak of the late war she hurried back to the Balkans, at her own expense, to offer her services to the Serbs The conditions were very bad and when the Serbs evacuated Uzsitsi in October, 1915, Dr Matthews decided to remain behind in charge of the military hospital to which she was surgeon She is said to have refused to undertake some of the medical work required of her by the Austro-German command, and she was taken to Belgrade as a prisoner of war on a charge of espionage These experiences undermined her health Dr Matthews was the author of various newspaper articles besides a number of books describing her adventures

Deputation on Irish Medical Affairs —A deputation from the Irish Medical Committee, consisting of Dr R J Rowlette, Dr A McBride, Dr J B McClancy, Dr J P Shanley, Dr M O'Brien, Dr T Hennessy, and Mr C H Gick recently waited on the Department of Local Government and Public Health in connexion with the following matters (1) transfer of medical officers under the Local Authorities (Officers and Employees) Act, 1926 , (2) private patients in county and district hospitals , (3) remuneration of Registrars of Births, Deaths and Marriages The deputation was received on behalf of the Minister by Mr E P McCarron, secretary, and Dr E F Stephenson, chief medical adviser to the department With regard to the transfer of medical officers, the deputation urged that the Minister should refuse to sanction any transfer made as promotion unless the officer transferred was entitled to promotion on the grounds of merit or long service in accordance with the intention of Section 5 of the Act Mr McCarron and Dr Stephenson agreed that the section quoted had for its object the promotion of existing officers on the lines stated by the deputation and undertook to convey its views to the Minister With regard to the admission of private patients to county hospitals, the deputation stated that whilst it was satisfied with the draft regulations forwarded by the department to the county health boards for adoption, these bodies did not show any desire to put them in force, and thus enable the doctors attached to the hospitals to arrange with private patients for payment for their medical attendance The deputation was informed that the department would use its influence, in the first instance, to have the draft regulations adopted by the health boards, and in the event of their refusal it would consider further representations from the profession In connexion with the increased remuneration for registrars, the deputation was invited to prepare a memorandum stating the position of these officials Mr McCarron and Dr Stephenson agreed that the fees paid at present for this work were inadequate More than 90 per cent. of the registrars in Ireland are dispensary doctors and the registration areas correspond to their dispensary districts

Droitwich Spa Brine Baths—At 3 30 P M to-day, April 29th, Mr Neville Chamberlain, Minister of Health, is to open extensions to the St Andrew's Brine Baths at Droitwich

Medical Golfing Society—The final of the Knock-out Tournament was won by Mr J. Cunning, the runner-up being Dr E Playfair

Gift to Birmingham Hospitals—Mr W. R. Morris, the motor-car manufacturer, who recently gave £104,000 to St Thomas's Hospital, has made a gift to the Lord Mayor of £25,000 for the Birmingham hospitals

Victoria Park Hospital, London—It was stated at the annual meeting last week of the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, that, owing to repeated deficits, the Saunderton Sanatorium has been closed The Research Institute given by the Prudential Assurance Company is approaching completion and will be opened formally in a few weeks' time It is hoped to raise a fund of £25,000 to enable the hospital to be enlarged and the sanatorium reopened

Mr Spahlinger and the Welsh National Memorial.—In a report presented to the Council of the Welsh National Memorial Association at its quarterly meeting in Chester on April 22nd the Medical Committee states "The application of public or other funds towards the Spahlinger Institute cannot be recommended by this committee The publicity campaign on behalf of the Spahlinger movement is to be deprecated as unjustified by the evidence so far adduced, and to be deplored as raising false hopes in the minds of sufferers from tuberculosis" The report is to be considered further at a special meeting of the Council, to be held at Shrewsbury in May

Analysis of Whole-fruit Jam—At Salford Police court on April 6th a manufacturing company was fined £20 and costs for selling to the city food inspector a pot of jam which was not of the quality and substance demanded The jam was advertised as being made from "freshly gathered whole fruit, ripe and perfect" Analysis showed that the sample contained cane-sugar, 26 parts, invert sugar, 32, glucose syrup and unfermentable matter, 6, insoluble solids and ash, 2, and water, 31 The jam was coloured with an aniline dye, and contained 20 parts per million of sulphur dioxide There was practically no whole fruit in it The sample had been made from fruit pulp preserved with sulphur dioxide A plea of guilty was entered, and it was stated that the advertising agents of the firm had made a mistake.

An Egyptian Congress Discussion of Tropical Diseases—A medical Congress for the discussion in particular of tropical diseases will take place in Cairo from *Dec 15th to 24th* The Committee of Honour includes the names of Profs J L Faure and A Loutfi el Sayed as Presidents, and Dr Andrew Balfour, Prof J W W Stephens, Dr Aldo Castellani, and Dr J G Thomson The Congress is being organised by the *Revue Pratique des Maladies des Pays Chauds*, and the Secretary-General is Dr Zeitoun (32, rue Gay Lussac, Paris) There will be committees for publication and propaganda purposes The scientific committee consists of Professors and Doctors Strong, R H Elliot, Aldo and Edward Perroncito Madsen, Warrington, Brumpt, Heckenroth Reynaud, Gilbert Sicard, Tuffier, Duval, Guiart, Besançon, Marchoux, Mandoul, Joyeux, Neveu, Lemaire, Nobécourt, Léon Bernard, Bertin-Sans, Jeannin, Victor Pauchet, Rieux, Radais, Audibert, Sorrel, Nattan-Larrier, Sartory, Vuillemin, Tanon, Brulé, Garin, Gaujoux, Leenhardt, Gougerot, Dalché, Morax, F Ramond, Ravaut, Rist, Sanarelli, and Tépine

The work of the Congress will be to receive communications and to organise conferences upon diseases generally, and especially upon tropical diseases, such as abscess of the liver, bilharziasis, oriental sore, leprosy, trypanosomiasis, kala-azar, trachoma, malaria, yellow fever, and undulant fever, general hygiene being considered The sections range over the whole of medicine and surgery and pathology, especially tropical, classified under bacteriology, urology, gastro-enterology, pharmacy, parasitology, dermatology, oto-rhino-laryngology, pediatrics, tuberculosis, hygiene, and veterinary medicine The titles of communications and their résumés must be sent to Dr Zeitoun before Oct 1st The time allowed for each of the communications will be 10 minutes and 20 minutes for the conferences

There will be an international Exhibition of Arts and Sciences, as applied to medicine, surgery, pharmacy, and sanitary administration A detailed programme with the conditions of membership can be obtained on request from the Organising Committee, and those joining the Congress will be granted facilities of travel and reduction of fares by the steamship companies on production of their cards of membership

Parliamentary Intelligence.

HOUSE OF COMMONS.

TUESDAY, APRIL 26TH.

THE House of Commons reassembled on this date after the Easter recess

Chemical Substances in Flour.

Mr DAY asked the Minister of Health whether, in view of the report of the departmental committee on the treatment of flour with chemical substances, he was considering the introduction of legislation to enforce a recommendation that flour should be in the product of the milling of wheat without the addition of any foreign substances, and, in view of the menace to the health of the nation, would he consider incorporating in any legislation introduced a clause that would in future prohibit the making or kneading of bread by hand by the introduction and installation of mechanical mixers—Mr CHAMBERLAIN replied No, Sir, I am not proposing, at present, to introduce legislation of the nature suggested

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole street, W

TUESDAY, May 3rd —5 30 P M, ORTHOPÆDICS Annual General Meeting Election of Officers and Council Paper Mr Norman D Royle (Sydney University) The Treatment of Spastic Paralysis by Sympathetic Ramisection (illustrated by "Kodascope" projector)

WEDNESDAY —5 30 P M, TROPICAL DISEASES AND PARASITOLOGY Annual General Meeting Election of Officers and Council Paper Dr P Y Lampe *Schistosoma mansoni* in Surinam (communicated by Dr J B Christopherson)

FRIDAY —5 P M, LARYNGOLOGY (Cases at 4 P M) Annual General Meeting Election of Officers and Council Paper and Demonstration Dr W Jobson Horne An Epidiascopic Demonstration of Chronic Hypertrophic Laryngitis with Some Observations on Treatment Cases and specimens will be shown by Mr A R Tweedie and others 8 30 P M, ANÆSTHETICS Annual General Meeting Election of Officers and Council

SATURDAY —OTOLOGY The Annual General Meeting will be held at 1, Wimpole street, W, at 9 15 A.M., when the election of Officers and Council will take place Immediately after, Members will proceed to the North-Eastern Fever Hospital, St Anne's road, Tottenham Transport is being arranged to and from the Hospital in time to be back at the Society's house by 12 30 P M Demonstrations of radiography of the mastoid in children, treatment by artificial sunlight, &c, will be given

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S W

TUESDAY, May 3rd —5 P M, Dr C Gordon Douglas The Coördination of the Respiration and Circulation with Variations in Bodily Activity (First Oliver Sharpey Lecture)

THURSDAY —5 P M (Second Oliver Sharpey Lecture)

UNIVERSITY COLLEGE, Gower street, W

TUESDAY, May 3rd, and following Wednesday and Friday —4 30 P M, Prof J S B Stopford Sensation and the Sensory Pathway (admission free)

KING'S COLLEGE, Strand, W C

TUESDAY, May 3rd —5 P M, Prof R J S McDowall Autonomic Nervous System (First of four free lectures)

INSTITUTE OF PATHOLOGY AND RESEARCH, St Mary's Hospital, W

THURSDAY, May 5th —5 P M, Prof C Prausnitz (Institute of Hygiene, Breslau) Experimental Researches on the Nature of the Bacteriophage

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W

MONDAY, May 2nd, to SATURDAY, May 7th —FELLOWSHIP OF MEDICINE Mr Goulden will give a demonstration on Tues, at the Royal London Ophthalmic Hospital at 1 P M Free to members of the medical profession —ROYAL FREE HOSPITAL, Gray's Inn-road W C Wednesday, 5 P M, Demonstration by Prof McIlroy 5 15 P M, Dr C B Heald lecture demonstration —ROYAL WATERLOO HOSPITAL, Waterloo road, S E Comprehensive course in Medicine.

Surgery and Gynæcology — London School of Tropical Medicine, Endsleigh-gardens, N W Tuesday, Dr Manson-Bahr Thursday, Dr Low Lecture-demonstrations —Maudsley Hospital, Denmark Hill, S E Afternoons only Special course in Psychological Medicine —London Lock Hospital, Dean street, W Comprehensive course Clinical teaching in Out patient Department and formal lectures —All Saints' Hospital, Vauxhall Bridge-road, S W Afternoons and evenings Demonstrations, including cystoscopies and lectures

Further information from the Secretary

NORTH-EAST LONDON POST GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N

Monday, May 2nd —2 P M, Medical Cases in the Wards 2 30 P M to 5 P M, Medical, Surgical, and Gynæcological Clinics Operations

Tuesday —2 30 P M to 5 P M, Medical, Surgical, Throat, Nose, and Ear Clinics Operations

Wednesday —2 30 P M to 5 P M, Medical, Skin, and Eye Clinics Operations

Thursday —11 30 A M, Dental Clinic 2 30 P M to 5 P M, Medical, Surgical, and Ear, Nose and Throat Clinics Operations

Friday —10 30 A M, Throat, Nose, and Ear Clinics 2 30 P M to 5 P M, Surgical, Medical, and Children's Diseases Clinics Operations

ROYAL NORTHERN HOSPITAL, Holloway-road, N

Tuesday, May 3rd —3 15 P M, Dr J W McNee Pathology and Treatment of Chronic Non-suppurative Arthritis

LONDON SCHOOL OF DERMATOLOGY, St John's Hospital, 49, Leicester-square, W.C

Tuesday, May 3rd —5 P M, Dr J A Drake Pyogenic Infections of the Skin

Thursday —5 P M, Dr H G Adamson Acne Vulgaris

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE

Tuesday, May 3rd —4 15 P M, Mr W R Douglas Hæmorrhoids

Friday —4 15 P M, Dr E B Leech Demonstration of Medical Cases

CHADWICK PUBLIC LECTURES

Tuesday, May 3rd —5 15 P M (at the Medical Society of London, 11, Chandos-street, W), Sir Thomas Legge The Teaching of Industrial Medicine

Appointments.

Idris, T H W, L M S S.A, has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Porlock District of the County of Somerset

Ironside, Redvers, M B, Ch B Aberd, M R C P Lond, Assistant Physician to the Hospital of SS John and Elizabeth, St John's Wood

Jones, Dilys M, M B, B Ch Wales, Woman Medical Officer to the Welsh Board of Health

McLay, K, M D St And, Medical Referee under the Workmen's Compensation Act for Selkirk County

Williams, R Lester, M B, B Ch Camb, F R C S Eng, Surgical Registrar at the London Lock Hospital, Dean street

Vacancies.

For further information refer to the advertisement columns

Bolton, County Borough Education Committee —Asst M O H, &c £600

Burton-on Trent —Asst M O H £600

Canterbury Dispensary, 60, *Burgate street* —Res M O £100

Cardiff City Mental Hospital, Whitchurch —Res Clin Asst £52 10s for 6 mos

Carshalton, Surrey, Queen Mary's Hospital for Children —Senior Asst M O £650

Central London Throat, Nose and Ear Hospital, Gray's Inn-road, W C —Hon Asst Out patient Registrar Also Res H S £75

Charing Cross Hospital, W C —P to Children's Dept Also Obstet Reg

Colchester Essex County Hospital —H S £150–£200

Croydon County Borough —Asst M O H, &c £600

Croydon General Hospital —Hon Jun S

Elizabeth Garrett Anderson Hospital Euston road —H P, Obstet Asst and Two H S's Each at rate of £50

Evelina Hospital Southwark, S E —Temp Asst Aural S

Freemason's Hospital and Nursing Home, 237, Fulham-road, Chelsea, S W —Res M O At rate of £250

Golden square Throat Nose, and Ear Hospital, Piccadilly Circus, W —H S £100

Herefordshire General Hospital Hereford —Res H P £100

Leeds, St James' Hospital —H P's and H S's Each £200

Newark Hospital —Res H S £200

North Middlesex Hospital, Edmonton N —Res M O £200

Norwich Norfolk and Norwich Hospital —Ophth Surgs, Lecturer on Pharmacology and Therapeutics Also H S £120

Paddington Board of Guardians —Outdoor Medical Services Asst M O £330.

Royal Free Hospital, Gray's Inn-road, W C —Res Anæsthetist Also Hon Asst Radiologist

Ryde, Royal Isle of Wight County Hospital —Anæsthetist £100.

Salford Royal Hospital —Med Reg £200

Sheffield Royal Hospital —Res Anæsthetist

Stamford, Rutland and General Infirmary —H S £150

Stirling District Mental Hospital, Larbert —Second Asst M O. £275

Stoke on-Trent, North Staffordshire Royal Infirmary —H P £150

Sudan Government —Laboratory Asst £324

Sudan Government, Wellcome Tropical Research Laboratories, Khartoum —Asst Bacteriologist £720

West Bromwich and District Hospital —Hon Phys

West London Hospital, Hammersmith-road, W —Hon Med. Radiologist Also Asst P

Western Ophthalmic Hospital, Marylebone road, N W —Hon Asst S

Westminster Hospital, Broad Sanctuary, S W —Fourth Asst, Phys

Wolverhampton and Staffordshire Hospital —H S At rate of £150

Woolwich and District War Memorial Hospital, Shooters Hill —Hon S's, P's, Radiologist and Anæsthetist

Births, Marriages, and Deaths.

BIRTHS.

Adams —On April 23rd, at Lynedoch-crescent, Glasgow, W, the wife of Douglas K Adams, M D, of a son

Campbell —On April 19th, at Lexham gardens, London, W, the wife of Dr J M H Campbell, of a daughter

Crowther —On Tuesday, the 26th April, at Bleak House, Penistone, to Florence Evelyn, the wife of Dr H A Crowther—a daughter

Hitchings —On April 14th, at Westfield, Hawkhurst, Kent, the wife of Dr D B Hitchings, of a son and daughter

Loveless —On April 11th at Queen's road, Ramsgate, the wife of Dr W B Loveless, of a daughter

Oram —On April 21st, at Lee terrace, Blackheath, S E, the wife of E H B Oram, M B, F R C S, of a son

MARRIAGES.

Anderson—Glaister.—On April 22nd, at Cathedral-square, U F Church, Glasgow, Frank E Anderson, M B, Ch.B, to Helen Douglas, only daughter of Dr and Mrs J N Glaister, Grafton-place, Glasgow

Clausen—Lennane —On Thursday, April 21st, Raymond John Clausen, M B, B S, to Elsie Edith *Lennane, L D S*

Herman—Franks —On April 20th, at the Parish Church, Tonbridge, Ashley Ernest Herman, O B E, F R C S Edin, to Noreen Joan, youngest daughter of Mr and Mrs Frank W Franks, Loampits, Tonbridge

Lloyd-Williams—De Lyons Pike —On April 23rd, at St John's Church Burgess Hill, Major Iorwerth Hubert Lloyd-Williams, M C, M B, R.A M C (T), to Gwladys, only daughter of Charles William and Lucy de Lyons Pike, of Burgess Hill

Lockyer—Morton —On April 26th, 1927, at St George's, Hanover square, by the Rev Canon Horsefield, D D, and the Rev Minos Devine, D D, Cuthbert Lockyer, M D., *F R C P*, *F R C S*, of Harley-street, W 1, to Violet Gwendoline Morton second daughter of the late Dr. Augustus Charles Morton and Mrs Morton, late of Aylsham, Norfolk

Weston—Morgan —On April 20th, at St. Germain's Church, Edgbaston, Bernard Archibald Astley Weston, M B, Ch B, D P H, to Margaret Morgan, only child of the late Lieut Patrick Morgan, R N, and the late Mrs Morgan, of Southport

DEATHS.

Robinson —On April 17th, at Guy's Hospital, John Robinson, M B, Ch B Edin, Medical Officer Dispensary, Canterbury

Watts —On April 21st at "The Ferns," The Burroughs, Hendon, George William Watts, L D S Eng F R.M S, aged 67.

N B —A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages, and Deaths

Queen Charlotte's Maternity Hospital —The annual report for 1926 points the moral of antenatal care and treatment. Of the 194 emergency patients 9 died, while in the 1719 booked cases only three mothers died Among the 1588 patients attended in their own homes there was only one maternal death. There were 5000 antenatal patients The consequences of the longer period of training for midwives are stated to have been serious, the applications for training falling off so considerably that the income of the school was reduced by about £1500, moreover, additional paid nurses have had to be employed Of late there has been some improvement and the committee of management hope that "the dislocation caused by the drastic alteration in the rules of the Central Midwives Board will gradually disappear" An appeal is to be made for a quarter of a million for an extension which will provide 70 more beds, and for some endowment and research facilities

Notes, Comments, and Abstracts.

NUMERICAL RELATION OF THE SEXES IN MAN

At a meeting of the Edinburgh Obstetrical Society on March 9th a paper on the Human Sex-Ratio was read by Dr F A E Crew, director of the Animal Breeding Research Department and lecturer in genetics in the University of Edinburgh

It is established, he said, that the sex of an individual is determined at the time of conception by the working of a mechanism which is revealed in the differences in chromosome content of the gametes The female elaborates only one kind of ovum, but the male elaborates two kinds of sperm in respect of the elements of the sex-determining mechanism There is a male-producing sperm which, fertilising any ovum, yields a male, and a female-producing, which gives rise to a female This being so, it follows that at all times after conception there is a sex-ratio If the two forms of sperm are produced in equal numbers, if each kind is equally viable and functional, and if male and female zygotes are equally viable, then the secondary sex-ratio which obtains at birth should be equality, as was also the primary sex-ratio at conception If the secondary sex-ratio is not equality, then the primary sex-ratio was not equality or else there must have been a sexually selective mortality operating prenatally If the primary sex-ratio was not equality then either the two forms of sperm were not produced in equal numbers or else they were not equally functional

Selective Mortality

In point of fact the secondary sex-ratio is not equality, though not far removed therefrom It would seem therefore that the primary sex-ratio is also equality and that there is no considerable sexually selective prenatal mortality But there are certain observations which refute this conclusion It was found that the sex-ratio of the population considered by age-groups shows a continuous swing from 55 2 males 100 females in the "85 years and over" group to 101 5 males 100 females in the group at the end of the second year of life, whilst the sex-ratio among individuals 1 year old is 102 100 and that among the newly-born 104 100 There is a definite selective elimination of the males throughout, save during those age-groups when reproductive stresses (menstruation, menopause) bear so heavily upon the female

If the amount and sex-incidence of mortality during the first year of life are examined it is found that the sex-ratio of deaths during the first three months is 131 5 males 100 females, during the second three months, 121 100, during the third, 120 100, and during the fourth 113 100 More boys than girls die during the first year of life and during this period the excess of male deaths over female steadily decreases as the end of the year is approached Again there is a sexually selective mortality at work It is seen that postnatally the sex-ratio is not static but shows a swing from nearly equality at birth to very low in senility It becomes necessary, therefore, to inquire whether or not this swing is entirely postnatal, whether or not it is but a continuation of a process that has been operating natally and prenatally An examination of the amount and sex-incidence of stillbirths and of abortions will throw light on this question

The sex-ratio of stillbirths is about 133 males 100 females, which is higher than that of live births In the case of abortions it is impossible to deal with complete records Embryonic deaths during the earliest months of pregnancy will not result in recognisable abortion and must remain unrecorded The amount of abortion is about 20 per cent. of all conceptions Moreover, this prenatal death affects the sexes differentially and the sex-ratio of abortuses becomes higher and higher as conception is approached It would seem indeed that the primary sex-ratio must be somewhere about 170 males 100 females If this is so, then the primary sex-ratio is profoundly different from the secondary and the latter is equality, because throughout prenatal life there is a selective elimination of the males Far more males than females are conceived and far more males than females perish during the period conception-parturition Of course it may be that the primary sex-ratio is equality and that those agencies which lead to fœtal death bear more heavily upon the females during the first two months or so of pregnancy and thereafter more heavily upon the males But there is no evidence that this is so

The high primary sex-ratio may be the result of a differential production of the two kinds of sperm It might be that it is physiologically more expensive for an individual to elaborate female-determining sperm than male-determining On the other hand, it is possible that the two kinds being produced in equal numbers exhibit different powers of fertilisation There may be differences in mortality, a differential susceptibility to adverse conditions within the female passage, a difference in the power to penetrate the egg, or a difference in the response to the attraction of the egg Whatever may be the cause, it can be assumed that the male-determining sperm is a more efficient fertilising agent than is the female-determining Of the differences between male and female which lead to a sexually selective elimination of one sex nothing is known All that can be said is that the male zygote is so constituted that it cannot withstand the stresses of the act of living as well as can the female

Racial Needs of Modern Man

Certain suggestions of interest emerge from the study of the human sex-ratio It will be granted that one result of advance in our knowledge of the physiology of development and of the infant will lead to the salving of the male Antenatal clinics and child welfare centres will tend to modify the sex-ratio and so emphasise what already may be looked upon as one of the many disharmonies exhibited by the human From the point of view of the sex-physiologist a sex-ratio of equality during the reproductive years is so unnecessary as to be almost absurd Such a ratio is necessary only in those forms of life in which the female elaborates as many eggs as her mate does sperm, assuming that it is a criterion of biological fitness that a species should exhibit a maximum fertility-rate In the case of the human, whilst the female now exhibits a restricted sexual life, a prolonged gestation, a reduced fecundity, the sexual attributes of the human male are the same as those of males of species in which both sexes are equally fecund

This habit of producing a secondary sex-ratio of equality has no relation to the racial needs of modern man It must be regarded as a physiological legacy, being the expression of a mechanism which served its primitive possessors well, but which has not become modified as mankind, evolving, shaped and re-shaped its social organisation One male in this matter is the equivalent of very many females, and a low sex-ratio together with polygyny would seem to be all that is required for the propagation of the species But, of course, it is not the only aim of mankind

A GUIDE TO GHENT

Mrs Sydney Stephenson dedicates to the memory of her husband a small and handy guide to the City of Ghent (London George Pulman and Sons, Ltd Pp 78 1*s* 6*d*), issued in time to be useful to those who attend the annual conference of the Royal Institute of Public Health to be held there from June 1st to 6th next After an interesting historical preface Mrs Stephenson takes the visitor round the city, giving the history of each building in turn, and pointing out carefully the places from which extensive views can be obtained A map is included and enough information to enable the visitor to get about with ease

YEAR BOOK OF UNIVERSITIES OF THE EMPIRE

The Year Book of the Universities of the Empire for 1927 has just been issued by Messrs G Bell and Sons (pp 858, 7*s* 6*d*) First published in 1914, it is edited by Walter H Dawson for the Universities Bureau of the British Empire, 50, Russell-square, W C 1 From it we learn that there are now 71 British universities, their total calendars occupying some 50,000 pages, and in the year book the attempt is made to extract from each of these documents—some exceedingly bulky—information likely to prove of interest to universities and colleges, to Government departments, clubs, schoolmasters, and to the public generally For the various sections dealing with Great Britain and Ireland, Canada, Australia, South Africa, and India introductory chapters give such information regarding the history, regulations, and practice as pertains to all the universities, while each heading comprises a directory of the office and members of the staff of the universities with their degrees, the general information includes useful facts concerning libraries, museums, and laboratories, as well as general arrangements and statistics A group of valuable appendices deal with the regulations for obtaining the diplomas of the professional colleges, and other faculties and associations having power to grant degrees and diplomas, explain the conditions governing admission to various professions and careers—matriculation and entrance examinations, define the admission of students from abroad to universities of the United Kingdom, and supply lists of inter-university scholarships and Fellowships, of grants for research, and of constituent and ancillary schools Thus we can learn the distribution of subjects in which the universities severally may be said to specialise, lists of centres of research outside the universities being added A new appendix provides lists of titles of theses accepted for research degrees, this is not as full as the compilers had wished to make it, but the intention expressed to perfect the list in the next issue of the year book is welcome, for we can understand that such a category would be of real service

DISEASE IN THE COTTON INDUSTRY

A CONFERENCE has recently been held in London between officials in the Home Office, representatives of leading cotton employers' associations, and the Card and Blowing Room Amalgamation, which is a trade-union body chiefly concerned with cotton spinning in the preparatory stages The object was to discuss the evils of dust in the cardrooms and ascertain if an agreement could be reached regarding preventive regulations which could be included in the next Factories Bill. The most interesting feature of the conference was the presentation of a report by the insurance section of the trade union containing a classification of the different illnesses from which cotton workers in this particular part of the industry suffer

The table giving the "nature of illnesses causing absence from work" deals with the years 1923–24 and 1926 for men, and 1923–24 for women. The returns collated from the society's records are as follows —

—	Men			Women	
	1923	1924	1926	1923	1924
Total membership	6883	6971	7058	25,409	25,366

Tubercular disease of joints, glands, skin, meninges, &c	—	4	11	20	29
Other illnesses	46	75	67	130	165
Totals	772	1217	1477	3903	4656

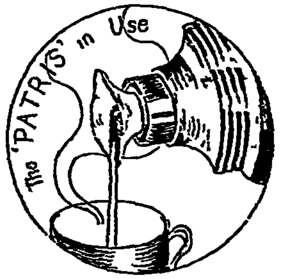
Another table dealing with disablement benefit states that during 1926, 256 persons were in receipt of this particular benefit Of this number, the following were certified to be suffering from—

Bronchitis	88 cases 6 deaths	343 68 } per thousand claims
Average age at date of claim		55 years 7 months
Average period of claim		1 year 9 months
Phthisis and tuberculosis	20 cases 3 deaths	78 150 } per thousand claims
Average age at date of claim		38 years
Average period of claim		2 years 8 months

These data display the women as experiencing more sickness than the men—which is usual for women between ages 15 and 45 as compared with men of similar age The age-distribution of the two sexes, however, is not given, but the men would nearly certainly be the older group They appear, during the comparable years 1923 and 1924, to have suffered more than the women from bronchitis and phthisis two diseases possibly attributable to greater exposure to dust, but less from anæmia, influenza, and colds In the absence of a table for comparison, stating the nature of illnesses experienced by a standard population, more definite deductions cannot be hazarded To day no such table exists for this country, while the data stated above are not presented in such a way as to permit comparison with the studies* made in America of sickness among industrial employees The whole subject of invalidity statistics is one of great importance, and it is already, we understand, engaging the attention of the Medical Research Council.

THE "PATRIS" SAFETY POURER

IT is difficult to pour out the contents of a vacuum flask in a steady stream, while droplets of the liquid often find their way inside the metal case, with a consequent rusting of the metal and rotting of the packing In order to overcome these disadvantages the "Patris" Company, 11, Thornfield-road, Bishop's Stortford, has placed on the market a device which, as is shown in the illustration, takes the form of a double-lipped glass funnel fitted to the mouth of the flask by means of a cork collar This allows the liquid to flow in a steady stream, splashing is entirely prevented The neck of the funnel is closed by an ordinary cork stopper The device will be appreciated by the user of the vacuum flask for ordinary purposes and particularly by the sick-room attendant, who may have to supply an invalid with a warm liquid at intervals



THE BEARDLESS SURGEON

Dr Herbert Smith (Ealing), writing in reference to the issue of THE LANCET which contained the report of the celebration of the Lister Centenary, refers to an episode which was chronicled in the *Westminster Gazette* last week, and suggests that the occurrence inaugurated "a beardless vogue" among surgeons "When I was house surgeon at —— hospital in 1881," the quotation runs, 'my colleague's whiskers were burnt off by the flaming-up of the 'Listerian Kettle' and, things being righted, a nurse remarked, 'Let us spray'" The occurrence may not have been unusual, while the question of disinfection of flowing hair formed a further invitation to the razor

TREATMENT OF ALOPECIA AND MENINGITIS

To the Editor of THE LANCET

SIR,—Kindly permit me to add to my notes on the use of iodine in cases of bursitis and adenitis (THE LANCET, April 2nd, p 741) a more definite description of the treatment of the aborting of abscesses

The most scrupulous cleansing of the surface of skin attacked, and then the use of a soft ointment of hydrarg perchloridi, 1 in 1000, liberally spread on lint cut to the size of the presenting abscess This should be repeated daily, in extensive abscesses, or even in those pouring out pus, I have never required more than a third dressing

Now I wish to give my treatment of meningitis This is what Sir Gilbert Barling consented to being used in my own case and with which he expressed his great pleasure (1) In alopecia first wash well the scalp and allow to dry thoroughly Then with a 2-inch square of soft sponge apply the following —

℞	Antim potass tart	ʒ ½
	Sp vin rect	℥ ½
	Aq destillat ad	℥ 4

When the scalp is still moist massage with the tips of the fingers for a few minutes In the case of females the hair should not be "put up" till completely dry, as an accumulation of the fluid in any one place would be followed by blistering, and this will not otherwise happen It should not be used more than twice a week This has given my scalp—quite bald at 75—a fairly presentable crop over nearly the whole surface. (2) In meningitis I have found splendid result by using the same salt, in the following prescription —

℞	Ant potass tart	gr i
	Syr cinnam	ʒ ½
	Aq font. ad	℥ 4

For a child of 1 month ʒi 4ta quaque hora, and if vomiting ensues reduce the number of doses It is well to use iced water to the head, and, if convulsions follow, to put an ice-bag along the spine from the neck to the sacrum, on for 20 minutes and off for ten I have found this give splendid results in adult cases of convulsions which defied all other treatment I meant to have concluded with three cases, and see I have gone one more.

I am Sir, yours faithfully.

Clevedon Somerset April 19th, 1927 E. T BURTON

OPHTHALMIC HOSPITAL IN JERUSALEM.

The report for 1926 of the Ophthalmic Hospital, founded in Jerusalem by the Order of St John, shows continued progress The number of new patients seen was 18,127 The number admitted to hospital was 1499 and the number of operations 4234 Of the new cases 7 6 per cent were blind in one eye, 2 5 in both—"blindness" being defined as inability to count fingers at one metre Of the blindness 70 per cent could be traced directly or indirectly to acute conjunctivitis The majority of the operations—about four-fifths—were performed for trachoma and its sequels In 1924 a scheme of ophthalmic clinics at six selected centres in Palestine was begun, staffed by specially trained doctors and nurses The work accomplished by these clinics shows *an increase of 50 per cent over that of 1925* This is a good record, but the report emphasises the need for this branch of the work to be placed on a permanent footing

A WARNING

We are informed that a man who may give the name of Dr Winter has been calling on professional men, particularly doctors and accountants, soliciting help and obtaining either money or clothing He may describe himself as an accountant and may say that he is an old Rugby and Oxford man, he has acquired a certain amount of information about these two places to be plausible He suffers from pulmonary tuberculosis and will quite likely state *that he has been at Yardley-road, Lenham, or Papworth* Sanatorium, the latter statements being true He has lately been "working" the Oxford-Slough area He is about 33, height 5 ft 5 in, of spare build, with bushy eyebrows, and rather penetrating downcast eyes which do not look one in the face Recently he was dressed in a dark grey suit and trilby hat Doctors are advised to take necessary precautions should he call on them

ANNUAL CHARITIES REGISTER

The importance of London charities in our national life is manifest from the figures contained in the Annual Charities Register and Digest[1] for 1927 All the charities in or available for London are classified here in a manner convenient for reference, and, excluding missionary and religious institutions, the turnover enumerated in the register amounted for the year 1924-25 to £14,965,307 This is a slightly less figure than marked the previous year, and no estimate for the later 12 months is forthcoming, but there is certainly a vast sum at issue The voluntary contributions included in this sum amounted to £6,192,883, while legacies accounted for £1,387,166, a fluctuating source of income designed in many cases to continue, by way of interest, the contribution of a dead supporter It should be noted that the number of the charities deriving their income from purely metropolitan sources, and expending it solely upon metropolitan cases, is comparatively small, but the number which, while located in the metropolis, derive their income from all parts of the kingdom, or afford assistance to applicants from all parts, is very large Both as a summary to the volume of charity and as a classified list of the institutions dispensing it, the book is a valuable one, while a full index makes reference easy The compilers are to be congratulated on their labours

HEALTH CONDITIONS IN BRUNEI

This State is situated between British North Borneo and Sarawak, and is 770 nautical miles distant from Singapore It consists of an area of about 2500 square miles containing a population of some 27,000 In 1885 the Sultan agreed that Great Britain should control his foreign relations and in 1905 under a further agreement a British Resident was appointed to advise and assist in the administration of the State Mr E E F Pretty, the present Resident, has just furnished to the Colonial Office his report for the year 1925 In the Medical Section it is stated that the general death-rate was lower than in the previous year, though the infantile mortality stood at 311 2 per mille as against 303 9 in 1924 The ratio of births to infantile deaths was 3 18 to 1 The general death-rate of 30 68 per mille showed a great improvement on the 1924 figures, and contrasted very favourably with the Labuan rate of 36 35 for 1925 All these figures tend to show that there must be a good general *average of fair health amongst the inhabitants, and* apparently the principal disease is malaria Beyond a few cases of mumps and chicken-pox, no contagious diseases There were 1285 vaccinations in Brunei and the out-stations, as against 1026 in 1924, and these figures, contrasted with 993 births in 1925 and 1090 in 1924, tend to show that the younger generation should be well protected against small-pox Dr H W Furnivall medical officer of Labuan, acted as medical officer of Brunei throughout the year, and paid in all 18 visits Sixty-four cases from Brunei territory were treated in Labuan Hospital A total of 2748 were treated in the Brunei Government Dispensary and out-stations, as against 2520 in 1924, most of these cases were among Government servants, police, and prisoners, and the nature of the diseases was chiefly of a trivial character The following is a comparative table of the principal diseases treated in 1924 and 1925 —

	1924	1925.
Malaria	215	204
Diarrhœa	64	78
Constipation	118	146
Bronchitis	89	110
Round worms	50	70

There were 37 Europeans resident on the average in the State, and they enjoyed good health though malaria claimed some victims in the out-stations One European child was born during the year 1925 was remarkable for its phenomenal rainfall, a maximum of 12 inches in the 24 hours, and a total of 213 inches for the year being recorded on Labu estate In Brunei town it rained on 226 days out of the 365

DEATHS AMONG SWEDISH SEAMEN

In *World's Health* for April Prof H Davide, of Stockholm, gives a classified list of deaths among Swedish seamen for each of the ten years 1911-1920 There were in all 6259 deaths, the number was greatly increased in 1918 by the influenza epidemic, which seems to have raised the deaths from "other infections" by 300, and those from pneumonia by 35, but to have left the deaths from tuberculosis unaffected Of all deaths one-quarter were due to accidents, as compared with one-half in the British merchant marine (and one-twelfth among men of seafaring ages in the general British population) Of the Swedish deaths 15 per cent (British 2½) are ascribed to tubercle, but *4 per cent*, as in England, to pneumonia In Sweden 4 per cent. are ascribed to malignant disease, but many less in England where, perhaps, men sooner cease to go to sea

Before joining a Swedish ship a sailor must be declared to have no disease unfitting him for service at sea, further, if he is going abroad he must not suffer from venereal disease in an infectious stage His diet is prescribed by law, as is also his accommodation on board (120 cubic and 15 square feet) During any period of 48 hours he must not work more than 24 if he is a sailor, more than 18 if an officer, more than *16 in the engine room* A medicine chest as prescribed must be provided, and the captain must give his men the treatment they need and send them to hospital if necessary Venereal disease in Sweden is treated at the expense of the State, which also provides treatment for seamen patients when they are abroad

Although there is no statement of the total numbers of seamen among whom the deaths occurred, and no attempt to elicit death-rates, the figures afford valuable information for comparison

Donations and Bequests —Among other bequests the late Miss Alice Fothergill, of Carlton-hill, St John's Wood, left £1000 each to the London Hospital, Dr Barnardo's Homes, and the Hospital for Sick Children, Great Ormond street, and £500 to their convalescent branch, £500 each to the National Society for the Prevention of Cruelty to Children the Metropolitan Convalescent Institution, the Royal Blind Pension Society, the London Society for Teaching the Blind, Sir William Treloar's Cripples' Home, and the Home for the Aged Poor, Ealing —Mr Samuel M Adams, of Bassett House, Wellingborough, left £800 to Manfield Orthopædic Hospital, *£250 each to* Wellingborough Cottage Hospital and Kettering Hospital, and after other legacies and bequests, the residue of the property to Northampton General Hospital —Mr Francis George Hoyle, of Armley, Leeds, left certain bequests to the poor of Armley, £500 to the Leeds General Infirmary, and £250 each to the Leeds Women's and Children's Hospital, the Leeds Tradesmen's Benevolent Institution, the Leeds Unmarried Women's Benevolent Institution, Sir Arthur Pearson's Hostel for Blinded Soldiers, and the Leeds Dispensary, and £100 to the Armley Nursing Association —Mrs Mary Amelia Gratrix, of West Point, Whalley Range, Manchester, who left £49,280, gave £250 to the *Northern* Counties Hospital for Incurables, and the residue of the property, after certain bequests, to her husband for life and then to the Manchester Royal Infirmary, the Missions to Seamen and the Manchester and Salford Branch of the National Lifeboat Institution —An anonymous donor has sent to the Lord Mayor of Liverpool a cheque for £1000 to the Royal Liverpool Seamen's Orphanage A short time ago Mr William Reed left to the Orphanage £72,000, which sum was reduced by death duties to nearly £50,000

ON

LOCAL EPILEPSY.

By GORDON HOLMES, C.M.G., C.B.E.,
M.D.Dubl., F.R.C.P.Lond.,
PHYSICIAN TO CHARING CROSS HOSPITAL AND TO THE NATIONAL HOSPITAL, QUEEN SQUARE.

THE problem of epilepsy is of perennial interest to the neurologist, and the numerous discussions that have been recently devoted to it, and the various hypotheses on its nature and origin that have been advanced, indicate only too clearly our ignorance of its essential pathogenesis. I have chosen as the subject for this lecture Local Epilepsy, as I believe a study of the simple phenomena produced by irritation of the brain, all of which are closely related to symptoms of the major disease, may throw light on the nature of the latter. Few of these observations are original, but they have been lost sight of or neglected by many who have lately overladen the literature of this subject. Excitability is one of the essential functions of nervous tissue, and *irritation* is a convenient term for the inducing of local activity in it by abnormal or pathological stimuli, which are certainly unlike in nature as well as in origin those that normally excite it. The term *discharge*, originally used by Hughlings Jackson, may be applied to the immediate response to such irritation.

The symptoms of local irritation of the brain are generally, in contrast to those of destructive lesions, paroxysmal or episodal. All the evidence we possess goes to show that these symptoms occur only when the grey matter is involved, and never when the white matter is alone affected. Further, they appear mainly when the cerebral cortex is excited; we have no convincing evidence that they result from disease of the basal ganglia or of the grey matter of the brain stem or spinal cord, though epileptiform phenomena have been observed with disease and experimental excitation of the pons Varolii. Physiological observations also confirm this view; while electrical stimulation of the cerebral cortex can give rise to epileptiform attacks—that is, tonic or clonic muscular contractions which are at first local, but tend to spread to neighbouring groups of muscles—similar stimulation of the subjacent white matter produces isolated twitches only. The fact that if a local spasm has once occurred it is more easily elicited again, and that if it persists for a time it is followed by temporary exhaustion of the part of the nervous system that initiates it, also confirms this, for the cortex is exhaustible while the conducting fibres are scarcely, if at all, so; and it is a property of the cortex that the occurrence of any physiological event in it facilitates recurrence of that event. Many different forms of disease may excite these epileptiform phenomena; hæmorrhages, softenings, patches of encephalitis and meningitis, tumours, and many other such affections may be effective—in fact, any disease which borders upon or even invades, but does not destroy or reduce seriously the functional capacity of, the tissues from which the symptoms may arise. If these are destroyed or seriously damaged the symptoms no longer occur.

It is probably only from the simplest and more highly organised afferent or recipient and efferent or motor cortical mechanisms that these phenomena can result, and they consequently always assume relatively simple forms. The local motor seizures which were first fully described and interpreted by Hughlings Jackson are due to excitation of the so-called motor area in the precentral gyrus and consist in tonic and clonic spasms of groups of muscles; they never take the form of purposive or more complicated acts, for these depend on the elaboration by other parts of the brain of motion patterns in which the serial order of contraction of various groups of muscles, as well as the force, the duration, and the rate of the contractions are already prearranged. The precentral gyrus probably plays little or no part in the formulation of these, but merely transmits to the lower motor centres what we call volitional impulses in the order determined by these patterns. We may, in fact, compare it with the keyboard of a piano by means of which the notes when sounded together and in sequence according to a prearranged score produce music, but which itself plays no part in determining harmony, and when struck by fingers not guided by a music pattern produces only discord. A purposeless discord of movement characterises an epileptic seizure. It is true that more complex movements of a purposive type occur in epilepsies, but only in the states of automatism that succeed or replace a seizure, and it is improbable that these have a local origin. Similarly, the sensations excited by irritation of the sensory cortex and projected to the periphery of the body are always simple and crude; they neither give rise to the illusion of peripheral stimulation, nor secondarily to the performance of complicated acts. Excitation of the cortical areas of vision and hearing lead to similar simple perceptions only.

LOCAL MOTOR EPILEPSY.

We may now consider the symptoms produced by *irritation* of the motor and sensory regions of the brain and of those parts of the cortex that receive impressions directly from the organs of special sense.

Local motor epilepsy was, it is true, recognised and described by Bravais in 1827, but it was Hughlings Jackson who first associated it with disease of the opposite hemisphere of the brain: his observations on it threw the first light on the localisation and organisation of the cortical motor apparatus. It consequently bears, by universal consent, the title "Jacksonian Epilepsy," originally proposed by Charcot. The chief features of Jacksonian epilepsy are well known, but its study helps to explain some of the phenomena of the rarer forms of local epilepsy.

Electrical stimulation of the brain, which was first introduced by Hitzig and Fritsch and employed with such noteworthy results by so many of our countrymen, as Ferrier, Schäfer, Horsley, and more recently by Sherrington, Leyton and Graham Brown, has confirmed and extended Jackson's original conclusions. It has revealed that in the cortex lying immediately in front of the fissure of Rolando there is a minute localisation, not rigid or even stable, it is true, of movements of the opposite side of the body. As the motor points are arranged in the cortex in a manner corresponding with the anatomical relations of the parts in which they initiate movement, a stimulus that spreads over the cortex excites a sequence of movements which spread or march in a more or less constant and regular manner from the segment of the body that is first convulsed. This is the essential feature of a Jacksonian attack; any chart of the motor representation of the cortex explains the march of the convulsions. The regularity of the march and the rate and extent to which the convulsion spreads depend on the nature of the excitation and probably, too, on the local condition of the brain.

The attack can be divided into two stages; the first consists of clonic movements, sometimes preceded or accompanied by tonic spasm. These clonic movements frequently spread so slowly and remain limited to one segment so long that it is possible to study them carefully. They consist of brisk tetanic contractions of all the muscles that coöperate in the movement; when it is flexion of the elbow, for instance, the brachialis anticus, supinator longus, and often the long flexors of the wrist and fingers contract as well as the biceps. In the clonic stages there seems to be always a relaxation of the antagonist muscles, of the triceps for example, when the elbow flexes. An interesting observation which I have been able to make repeatedly is that if the limb which is in clonic spasm is moved passively into the extreme position to which the clonically contracting muscles would bring it, the spasm ceases in these muscles and spreads to another set, generally to their antagonists. If, for instance, while there is

OPHTHALMIC HOSPITAL IN JERUSALEM.

THE report for 1926 of the Ophthalmic Hospital, founded in Jerusalem by the Order of St John, shows continued progress The number of new patients seen was 18,127 The number admitted to hospital was 1499 and the number of operations 4234 Of the new cases 7 6 per cent were blind in one eye, 2 5 in both—"blindness" being defined as inability to count fingers at one metre Of the blindness 70 per cent could be traced directly or indirectly to acute conjunctivitis The majority of the operations—about four-fifths—were performed for trachoma and its sequels In 1924 a scheme of ophthalmic clinics at six selected centres in Palestine was begun, staffed by specially trained doctors and nurses The work accomplished by these clinics shows an increase of 50 per cent over that of 1925 This is a good record, but the report emphasises the need for this branch of the work to be placed on a permanent footing

LOCAL EPILEPSY

By GORDON HOLMES, C.M.G., C.B.E.,
M.D. Dubl., F.R.C.P. Lond.,
PHYSICIAN TO CHARING CROSS HOSPITAL AND TO THE NATIONAL HOSPITAL, QUEEN SQUARE

THE problem of epilepsy is of perennial interest to the neurologist, and the numerous discussions that have been recently devoted to it, and the various hypotheses on its nature and origin that have been advanced, indicate only too clearly our ignorance of *its essential pathogenesis* I have chosen as the subject for this lecture Local Epilepsy, as I believe a study of the simple phenomena produced by irritation of the brain, all of which are closely related to symptoms of the major disease, may throw light on the nature of the latter Few of these observations are original, but they have been lost sight of or neglected by many who have lately overladen the literature of this subject Excitability is one of the essential functions of nervous tissue, and *irritation* is a convenient term for the inducing of local activity in it by abnormal or pathological stimuli, which are certainly unlike in nature as well as in origin those that normally excite it The term *discharge*, originally used by Hughlings Jackson, may be applied to the immediate response to such irritation

The symptoms of local irritation of the brain are generally, in contrast to those of destructive lesions, paroxysmal or episodal All the evidence we possess goes to show that these symptoms occur only when the grey matter is involved, and never when the white matter is alone affected Further, they appear mainly when the cerebral cortex is excited, we have no convincing evidence that they result from disease of the basal ganglia or of the grey matter of the brain stem or spinal cord, though epileptiform phenomena have been observed with disease and experimental excitation of the pons Varolii Physiological observations also confirm this view, while electrical stimulation of the cerebral cortex can give rise to epileptiform attacks—that is, tonic or clonic muscular contractions which are at first local, but tend to spread to neighbouring groups of muscles—similar stimulation of the subjacent white matter produces isolated twitches only The fact that if a local spasm has once occurred it is more easily elicited again, and that if it persists for a time it is followed by temporary exhaustion of the part of the nervous system that initiates it, also confirms this, for the cortex is exhaustible while the conducting fibres are scarcely, if at all, so, and it is a property of the cortex that the occurrence of any physiological event in it facilitates recurrence of that event Many different forms of disease may excite these epileptiform phenomena, hæmorrhages, softenings, patches of encephalitis and meningitis, tumours, and many other such affections may be effective—in fact, any disease which borders upon or even *invades, but* does not destroy or reduce seriously the functional capacity of, the tissues from which the symptoms may arise If these are destroyed or seriously damaged the symptoms no longer occur

It is probably only from the simplest and more highly organised afferent or recipient, and efferent or motor cortical mechanisms that these phenomena can result, and they consequently always assume relatively simple forms The local motor seizures which were first fully described and interpreted by Hughlings Jackson are due to excitation of the so-called motor area in the precentral gyrus, and consist in tonic and clonic spasms of groups of muscles, they *never take* the form of purposive or more complicated acts, for these depend on the elaboration by other parts of the brain of motion patterns in which the serial order of contraction of various groups of muscles as well as the force, the duration, and the rate of the contractions are already prearranged The precentral gyrus probably plays little or no part in the formulation of these, but merely transmits to the lower motor centres what we call volitional impulses in the order determined by these patterns We may, in fact compare it with the keyboard of a piano by means of which the notes when sounded together and in sequence according to a prearranged score produce music, but which itself plays no part in determining harmony, and when struck by fingers not guided by a music pattern produces only discord A purposeless discord of movement characterises an epileptic seizure It is true that more complex movements of a purposive type occur in epilepsies, but only in the states of automatism that succeed or replace a seizure, and it is improbable that these have a local origin Similarly, the sensations excited by irritation of the sensory cortex and projected to the periphery of the body are always simple and crude, they neither give rise to the illusion of peripheral stimulation, nor secondarily to the performance of complicated acts Excitation of the cortical areas of vision and hearing lead to similar simple perceptions only

LOCAL MOTOR EPILEPSY

We may now consider the symptoms produced by irritation of the motor and sensory regions of the brain and of those parts of the cortex that receive impressions directly from the organs of special sense

Local motor epilepsy was, it is true, recognised and described by Bravais in 1827, but it was Hughlings Jackson who first associated it with disease of the opposite hemisphere of the brain, his observations on it threw the first light on the localisation and organisation of the cortical motor apparatus It consequently bears, by universal consent, the title "Jacksonian Epilepsy," originally proposed by Charcot The chief features of Jacksonian epilepsy are well known, but its study helps to explain some of the phenomena of the rarer forms of local epilepsy

Electrical stimulation of the brain, which was first introduced by Hitzig and Fritsch and employed with such noteworthy results by so many of our countrymen, as Ferrier, Schäfer, Horsley, and more recently by Sherrington, Leyton, and Graham Brown, has confirmed and extended Jackson's original conclusions It has revealed that in the cortex lying immediately in front of the fissure of Rolando there is a minute localisation, not rigid or even stable, it is true, of movements of the opposite side of the body. As the motor points are arranged in the cortex in a manner corresponding with the anatomical relations of the parts in which they initiate movement, a stimulus that spreads over the cortex excites a sequence of movements which spread or march in a more or less constant and regular manner from the segment of the body that is first convulsed This is the essential feature of a Jacksonian attack, any chart of the motor representation of the cortex explains the march of the convulsions The regularity of the march and the rate and extent to which the convulsion spreads depend on the nature of the excitation, and probably, too, on the local condition of the brain.

The attack can be divided into two stages the first consists of clonic movements, sometimes preceded or accompanied by tonic spasm These clonic movements frequently spread so slowly and *remain limited* to one segment so long that it is possible to study them carefully They consist of brisk tetanic contractions of all the muscles that cooperate in the movement, when it is flexion of the elbow, for instance, the brachialis *anticus*, supinator longus, and often the long flexors of the wrist and fingers contract as well as the biceps In the clonic stages there seems to be always a relaxation of the antagonist muscles, of the *triceps*, for example when the elbow flexes An interesting observation which I have been able to make repeatedly is that if the limb which is in clonic spasm is moved passively into the extreme *position* to which the clonically contracting muscles would bring it, the spasm ceases in these muscles and spreads to another set, generally to their antagonists If, for instance, while there is

The first, a man of middle age, was well in every respect until about two months before I saw him. Then one day, while sitting at home, he suddenly got a numb tingling feeling in his right great toe and on the inner aspect of the front of this foot. The tingling spread, at first slowly to his other toes, and then more rapidly up the leg reaching almost as high as the groin As the tingling progressed up his leg it diminished gradually in his foot and toes, leaving behind it a numbness, and probably an actual loss of sensation, which persisted nearly an hour. He had later a large number of similar seizures, all of which began similarly with tingling in the right great toe. In some the paræsthesiæ were limited to the leg in others they spread up the right side of his trunk, and on reaching the shoulder passed down the arm to his fingers In a few of the severer attacks he lost consciousness In the slighter seizures there was nothing resembling clonic involuntary spasms, but the patient often moved the limb or "squirmed it about" in a purposive manner. as if to relieve the disagreeable sensations True clonic spasms of the leg did, however occur in some of the attacks, due probably to spread of the discharge of the motor cortex. As he had other symptoms of a cerebral tumour he was operated upon and a growth was found beneath but close to the cortex of the upper parietal lobule. Its position here explains the onset of paræsthesiæ in his foot, while the anatomical arrangement of the sensory foci for the different segments of the limbs determined the mode of its spread

The second case was one of gunshot injury over the lower part of the right parietal lobe The patient was an intelligent man and gave a clear account of his symptoms Immediately after the wound there was a considerable degree of weakness and of sensory disturbance on his left side, chiefly in the arm, but these had disappeared leaving only slight defects of the sense of position and of localisation in his left hand. Since the infliction of the wound he has been subject to left-sided attacks, which have become less severe and less frequent. They always begin with a tingling in the left two middle fingers which gradually extends to the other fingers covers the whole hand and slowly ascends the forearm generally stopping at the elbow but occasionally reaching the shoulder In some attacks tingling in the left side of his face sets in soon after it appears in the fingers, but it is never so intense as in his hand. No involuntary movements of the limb occur, but as the tingling spreads and becomes more intense the hand grows weak or even powerless

This stage of the attack may last up to 15 minutes but it is generally shorter in duration. It is followed by a "deadness" and "loss of feeling" in the hand and forearm, and on one occasion when I was able to examine him at this stage, I found complete loss of the sense of position in the limb, as well as great reduction of all forms of cutaneous sensibility up to the elbow. This gradually diminished from the elbow downwards, finally disappearing from the fingers in about half an hour.

In this case the periodic discharges commencing by excitation of that portion of the sensory cortex where the fingers are represented always spread up the post-central gyrus to the level of the representation of the elbow or shoulder, and sometimes down it into the facial area. Further, as in all such severe attacks the paræsthesiæ were followed by actual loss of sensation As Sittig has pointed out recently, the paræsthesiæ do not always spread from part to part in an order which corresponds strictly to the arrangement of the cortical representations of these parts, but this is true of some Jacksonian motor attacks too.

The post-paroxysmal loss of sensation presents many features of interest. Some years ago I saw a case with severe left-sided sensory epilepsy in which it was possible to study it carefully The attacks always began with tingling in the left arm sometimes so intense as to be actually painful and then spread slowly to the shoulder down the trunk, and into the left leg. In some of the attacks clonic convulsions of the same distribution occurred but they always followed the tingling As the paræsthesiæ spread to each segment of the limb sensation in it became dulled and finally disappeared so that when the active phase of the attack was over the whole of the left limbs and that side of the trunk and face to a lesser degree were completely anæsthetic to all stimuli Sensation returned slowly and in the same manner after each attack I observed First the anæsthesia began to recede from the middle line of the trunk towards the roots of the limbs in the limbs cutaneous sensation returned gradually from the shoulder and hip towards the hand and foot One surprising fact which I repeatedly observed in other cases too was that in the limbs the upper level of the anæsthesia was usually sharp. corresponding roughly to a circular line around the limb; at one moment, for instance. it might be limited above by a line around the elbow. and some minutes later by one equally sharp around the middle of the forearm.

These observations bring out some points of interest. In the first place there is no definite evidence that the representation of the limbs in the sensory cortex corresponds to their anatomical segments; though in cortical hemiplegia there may be a greater disturbance of sensation in the hand and foot than in the arm or thigh observations on the effects of destructive lesions of the cortex certainly never reveal such a sharp limit of the anæsthesia as is found after epileptiform seizures. In the second place. forms of sensation are lost with which the cortex has little or nothing to do. There may be, for example. total cutaneous analgesia or thermanæsthesia for a time, though the perception of pain and temperature is possible when the whole sensory cortex has been destroyed. We must consequently assume that physiological disturbances, which we may here again attribute to exhaustion of the grey matter. affects subcortical centres too in this case probably the optic thalmus.

A few patients subject to focal sensory epilepsy have informed me that occasionally, and apparently independently of the characteristic attacks the part usually involved by the *paræsthesiæ may suddenly* become numb or "dead." in other words. anæsthetic. In a woman with the symptoms of a tumour of the right parietal lobe, a sudden but transient loss of sensation in her left hand was one of the most prominent symptoms; I have not, however. had the opportunity of examining any patient while this disturbance was present. It is therefore obvious that focal sensory epileptic seizures present many close analogies with Jacksonian motor attacks They begin locally and the spread of the sensory phenomena that constitutes them is determined by the topographical arrangement in the cortex of the representation of different segments of the body; they are usually followed by loss of sensation and may be occasionally replaced by transient anæsthesia

VISUAL EPILEPSY.

Attacks to which this term may be applied have been frequently observed. They have been well described by Gowers. who in his last paper on the subject recorded two cases in which I was able to observe the patients during several attacks Since the war there have been more opportunities of investigating such attacks

The cortical visual centres lie around the calcarine fissures, that in each hemisphere corresponding to the homonymous halves of the two retinæ and receiving therefore impressions from the opposite halves of the visual fields It is definitely determined too, that there is a detailed localisation in each cortical visual area, its posterior part corresponding to macular or central and its anterior part to peripheral vision, while the upper part of the area receives impressions from the lower part of the field and the lower from the upper. Perceptions due to the irritation of any part of the visual cortex are projected to the corresponding point in the field of vision and consequently if the discharge spreads over the cortex the phenomena perceived appear to the patient to move through the opposite half of the binocular field of vision

This can be illustrated by one of Gowers cases in which I was able to observe the patient during many attacks, some of which lasted ten minutes or longer They commenced with the appearance of several small spheres, white in the centre with an intermediate zone of blue and outside this a ring of red, immediately to the left of the point at which the patient gazed, from here they moved either at a uniform rate or in jerks to the left and downwards. As the patient remained conscious during the attacks he was able to indicate the position to which he referred them. When the spectra passed further from the fixation point the colours disappeared from them Almost immediately after their appearance vision in the left halves of the fields became dim and the loss quickly amounted to a left complete hemianopia which persisted for several minutes after the vigorous clonic flexion of the forearm, the elbow be flexed as far as possible, the spasm may at once shift to its extensors This may be due to the new position altering the relative excitability of the cortical flexor and extensor points, Sherrington has pointed out how unstable these points are, and we shall find later that peripheral stimuli can influence the reactions excited from them

The second stage is one of motor paresis following the clonic movements This may vary in degree and duration, occasionally it is slight and transient, but when the spasms have been severe no volitional movement may be possible for a considerable time, even hours may elapse before power returns Jackson, who observed this post-epileptic paresis in some of his earlier cases, accepted Todd's explanation that it is due to exhaustion of the cortical grey matter, a hypothesis that is now generally accepted The paralysis is always flaccid and is accompanied by exaggerated reflexes, and by Babinski's sign if the leg is involved

An interesting fact not generally recognised, is that convulsive attacks are occasionally replaced by other manifestations, the most common of which is a sudden but transient paresis of that portion of the limb which in other attacks is involved in the clonic spasms Usually the primary paresis appears in the part in which the spasms commence, but it may affect another region the cortical representation of which is adjacent to the site of discharge, in a case recorded by Hughlings Jackson, for instance, clonic movements of the face were immediately followed by paralysis of the hand of the same side The following case is a good example of one in which at times defect or negative symptoms only occurred

Case 1 —The patient received a gunshot wound of his head in the region of the posterior end of the second left frontal convolution Some months after being wounded he began to have epileptiform seizures of the Jacksonian type All began with a clonic flexion of the right thumb and fingers, particularly of the index and medius Within a few seconds all the fingers were involved in clonic flexion spasms, which then spread to the wrist, and later to the elbow Many attacks ended at this stage, but in others the arm was abducted and protracted at the shoulder, the clonic twitching extended to the right side of his face, and jerked his head and eyes to the right Each attack was followed by weakness of the right fingers and wrist which, according to his own story, varied with the severity and duration of the clonic spasms No numbness, tingling, or other sensory disturbance accompanied the clonic movements

Sometimes, however, attacks occurred in which there were neither tonic nor clonic spasms, or movements of any kind, he simply lost power suddenly and without any warning in the hand If reading, his book might fall unexpectedly, or his cane might drop from his hand as he walked The loss of power was complete for a time, but after a few minutes voluntary movement returned and gradually reached the normal

I have seen several other patients with Jacksonian motor epilepsy who were subject to similar sudden transient palsies of the limb or segment of the limb in which at other times the convulsion commenced The immediate cause of this palsy is doubtful Higier, who described one case, suggests that in certain circumstances the cortical inhibition of the antagonists may predominate over the excitation It is difficult to explain it by this hypothesis; it seems more likely that it is due to a primary inhibition instead of waves of excitation spreading over the cortical motor elements, a change perhaps similar to that which causes loss of consciousness in epilepsy and the sudden relaxations of the muscles leading to "falls," which often occur in it

Such observations show that a local lesion producing a functional instability of part of the so-called motor cortex of the brain may, in addition to predisposing to local epileptiform phenomena, which are frequently followed by temporary loss of power in the convulsed part, be the immediate cause of such negative symptoms as a primary transient paralysis of regions of the body represented in its neighbourhood

The cortical mechanisms of speech are frequently involved in right-sided epileptiform seizures but invariably, I believe in a negative manner This is an important point, as it suggests that the functions of the more highly evolved cerebral mechanisms are arrested by factors which produce positive symptoms in less highly evolved mechanisms In epilepsy the stream of consciousness is similarly arrested In such seizures, as in general epileptic convulsions, the patient may emit an inarticulate cry or groan, but never a word or a series of sounds that can be regarded as symbols of thought, or which suggest in any way the expression of an emotion or idea In many instances these sounds are due to forcible expiration or inspiration through the closed glottis On the other hand, a complete or partial aphasia may accompany or follow the seizure This aphasia is usually so transient that it is scarcely possible to analyse it fully even when the opportunity of observing it is offered Sometimes the main difficulty is the utterance of words, but in other cases comprehension of speech and evocation of correct words to reply to a question or to express an idea are disturbed

I have recently had several opportunities of observing such a temporary aphasia in a lady in whom a left-sided temporal tumour was removed four years ago She has been recently subject to numerous epileptiform seizures, in many of which consciousness is not lost These attacks often commence with a disgusting smell and an unpleasant taste, then she passes into an abnormal mental state similar to Jackson's "dreamy state," and the right side of her face may twitch Though she remains conscious speech is completely lost from the commencement of the attack, questions and other stimuli evoke no response As the attack passes off she utters unintelligible jargon sounds and during the succeeding few minutes uses wrong words to express herself The speech returns gradually and is normal again in from three to five minutes During part of the attack she is unable to comprehend spoken speech

Focal Sensory Epilepsy

Focal sensory epilepsy has attracted less notice, perhaps since it is less commonly met with, but mainly because it does not present itself in such a striking and dramatic form to the observer, for it consists of purely subjective symptoms It is not, however, rare, especially since the war has given us a large number of men with gunshot wounds of the head involving the sensory cortex

Our knowledge of the limits and extent of the sensory cortex is less definite than of those of the motor area, but clinical observations, which are supported at least by experimental work, go to show that it lies wholly behind the fissure of Rolando It is possible that the recognition of the position of our limbs in space may be partly subserved by the precentral cortex, but this is certainly not concerned with any other form of sensation The occipitalward limit of the sensory area is still undetermined, but it probably extends as far as the supramarginal gyrus. That there is a localisation in the sensory cortex analogous to the motor localisation in the precentral area there can be no doubt; the lower limb is represented at and around the apex of the hemisphere, and the trunk, arm, and head in this order below it This anatomical arrangement of the sensory representation of different parts of the body determines the mode of spread of the sensory phenomena which are excited by local irritation of the cortex and projected to the surface

These vary in nature, but are generally described by the patient as numbness or tingling, or occasionally as a "deadness" or loss of feeling These are all positive symptoms, by which I mean phenomena added to the normal state and due directly to over activity of the corresponding parts of the cortex This is generally true even of those sensations described by the patient as "deadness" or "loss of feeling," these being merely alternative terms for numbness which is a positive phenomenon A much rarer symptom is a sensation of movement, then the patient has the feeling that a part of the body, generally a segment of a limb, has moved in some definite direction although there has been actually no displacement of that part As far as I am aware, there is never the illusion of more complicated acts

Two cases I have recently seen illustrate more common forms of focal sensory epilepsy

The first, a man of middle age, was well in every respect until about two months before I saw him Then one day, while sitting at home, he suddenly got a numb tingling feeling in his right great toe and on the inner aspect of the front of this foot The tingling spread, at first slowly to his other toes, and then more rapidly up the leg, reaching almost as high as the groin As the tingling progressed up his leg it diminished gradually in his foot and toes, leaving behind it a numbness, and probably an actual loss of sensation, which persisted nearly an hour He had later a large number of similar seizures, all of which began similarly with tingling in the right great toe In some the paræsthesiæ were limited to the leg, in others they spread up the right side of his trunk, and on reaching the shoulder passed down the arm to his fingers In a few of the severer attacks he lost consciousness In the slighter seizures there was nothing resembling clonic involuntary spasms, but the patient often moved the limb, or "squirmed it about," in a purposive manner, as if to relieve the disagreeable sensations True clonic spasms of the leg did, however, occur in some of the attacks, due probably to spread of the discharge of the motor cortex As he had other symptoms of a cerebral tumour he was operated upon and a growth was found beneath but close to the cortex of the upper parietal lobule Its position here explains the onset of paræsthesiæ in his foot, while the anatomical arrangement of the sensory foci for the different segments of the limbs determined the mode of its spread

The second case was one of gunshot injury over the lower part of the right parietal lobe The patient was an intelligent man and gave a clear account of his symptoms Immediately after the wound there was a considerable degree of weakness and of sensory disturbance on his left side, chiefly in the arm, but these had disappeared leaving only slight defects of the sense of position and of localisation in his left hand Since the infliction of the wound he has been subject to left-sided attacks, which have become less severe and less frequent They always begin with a tingling in the left two middle fingers which gradually extends to the other fingers, covers the whole hand, and slowly ascends the forearm, generally stopping at the elbow but occasionally reaching the shoulder In some attacks tingling in the left side of his face sets in soon after it appears in the fingers, but it is never so intense as in his hand No involuntary movements of the limb occur, but as the tingling spreads and becomes more intense the hand grows weak or even powerless This stage of the attack may last up to 15 minutes, but it is generally shorter in duration It is followed by a "deadness" and "loss of feeling" in the hand and forearm, and on one occasion when I was able to examine him at this stage, I found complete loss of the sense of position in the limb, as well as great reduction of all forms of cutaneous sensibility up to the elbow This gradually diminished from the elbow downwards, finally disappearing from the fingers in about half an hour

In this case the periodic discharges, commencing by excitation of that portion of the sensory cortex where the fingers are represented, always spread up the post-central gyrus to the level of the representation of the elbow or shoulder, and sometimes down it into the facial area Further, as in all such severe attacks, the paræsthesiæ were followed by actual loss of sensation As Sittig has pointed out recently, the paræsthesiæ do not always spread from part to part in an order which corresponds strictly to the arrangement of the cortical representations of these parts, but this is true of some Jacksonian motor attacks too

The post-paroxysmal loss of sensation presents many features of interest Some years ago I saw a case with severe left-sided sensory epilepsy in which it was possible to study it carefully The attacks always began with tingling in the left arm, sometimes so intense as to be actually painful, and then spread slowly to the shoulder, down the trunk, and into the left leg In some of the attacks clonic convulsions of the same distribution occurred, but they always followed the tingling As the paræsthesiæ spread to each segment of the limb sensation in it became dulled and finally disappeared, so that when the active phase of the attack was over the whole of the left limbs and that side of the trunk and face to a lesser degree, were completely anæsthetic to all stimuli Sensation returned slowly and in the same manner after each attack I observed First the anæsthesia began to recede from the middle line of the trunk towards the roots of the limbs, in the limbs cutaneous sensation returned gradually from the shoulder and hip towards the hand and foot One surprising fact which I repeatedly observed in other cases too was that in the limbs the upper level of the anæsthesia was usually sharp, corresponding roughly to a circular line around the limb, at one moment, for instance, it might be limited above by a line around the elbow, and some minutes later by one equally sharp around the middle of the forearm

These observations bring out some points of interest In the first place, there is no definite evidence that the representation of the limbs in the sensory cortex corresponds to their anatomical segments, though in cortical hemiplegia there may be a greater disturbance of sensation in the hand and foot than in the arm or thigh, observations on the effects of destructive lesions of the cortex certainly never reveal such a sharp limit of the anæsthesia as is found after epileptiform seizures In the second place, forms of sensation are lost with which the cortex has little or nothing to do There may be, for example, total cutaneous analgesia or thermanæsthesia for a time, though the perception of pain and temperature is possible when the whole sensory cortex has been destroyed We must consequently assume that physiological disturbances, which we may here again attribute to exhaustion of the grey matter, affects subcortical centres too, in this case probably the optic thalmus

A few patients subject to focal sensory epilepsy have informed me that occasionally, and apparently independently of the characteristic attacks, the part usually involved by the paræsthesiæ may suddenly become numb or "dead," in other words, anæsthetic In a woman with the symptoms of a tumour of the right parietal lobe, a sudden but transient loss of sensation in her left hand was one of the most prominent symptoms, I have not, however, had the opportunity of examining any patient while this disturbance was present It is therefore obvious that focal sensory epileptic seizures present many close analogies with Jacksonian motor attacks They begin locally and the spread of the sensory phenomena that constitutes them is determined by the topographical arrangement in the cortex of the representation of different segments of the body, they are usually followed by loss of sensation, and may be occasionally replaced by transient anæsthesia

VISUAL EPILEPSY

Attacks to which this term may be applied have been frequently observed They have been well described by Gowers, who in his last paper on the subject recorded two cases in which I was able to observe the patients during several attacks Since the war there have been more opportunities of investigating such attacks

The cortical visual centres lie around the calcarine fissures, that in each hemisphere corresponding to the homonymous halves of the two retinæ and receiving therefore impressions from the opposite halves of the visual fields It is definitely determined, too, that there is a detailed localisation in each cortical visual area, its posterior part corresponding to macular or central and its anterior part to peripheral vision, while the upper part of the area receives impressions from the lower part of the field and the lower from the upper. Perceptions due to the irritation of any part of the visual cortex are projected to the corresponding point in the field of vision, and consequently if the discharge spreads over the cortex the phenomena perceived appear to the patient to move through the opposite half of the binocular field of vision

This can be illustrated by one of Gowers' cases in which I was able to observe the patient during many attacks, some of which lasted ten minutes or longer They commenced with the appearance of several small spheres, white in the centre with an intermediate zone of blue and outside this a ring of red, immediately to the left of the point at which the patient gazed, from here they moved either at a uniform rate or in jerks to the left and downwards As the patient remained conscious during the attacks he was able to indicate the position to which he referred them When the spectra passed further from the fixation-point the colours disappeared from them. Almost immediately after their appearance vision in the left halves of the fields became dim and the loss quickly amounted to a left complete hemianopia which persisted for several minutes after the attacks ceased, then disappearing gradually from the centre towards the periphery

In all attacks the eyes deviated towards the left and the head turned in the same direction as soon as the visual spectra appeared This deviation of the eyes and head was at first tonic but later became clonic, it could be controlled to some extent by the patient In some of the attacks at least it was probably secondary to the visual spectra, the gaze being directed reflexly towards the point in space to which the spectra were projected This man had in all probability a cerebral tumour, but its position in the brain was not determined Gowers assumed that the symptoms were due to a lesion in the neighbourhood of the angular gyrus

Gowers records in the same lecture another case, that of a girl, aged 9, who was under my observation for some years She had been, since receiving an injury to her head at the age of 3½ years, subject to right-sided epileptiform attacks most of which began with the appearance of a bright light in the right halves of her visual fields, which she spoke of as "twinkles," probably because it scintillated Frequently there were colours in it As soon as it appeared she invariably brought her hand to the outer side of her right eye "to rub it away" Her head and eyes turned *slowly to the right, she lost consciousness, and developed* tonic and clonic spasms in her right limbs On regaining consciousness there was a defect of vision in each eye to the right of the fixation-point, occasionally a complete hemianopia which cleared up quickly Mr Sargent discovered a cyst, probably the result of a traumatic hæmorrhage, in the left angular gyrus, but it is possible that there were other lesions nearer the calcarine area

Similar attacks of visual epilepsy have been frequently observed in men who had received gunshot wounds in the occipital region Several such cases informed me that some time after the infliction of the wound, or on regaining consciousness after it, they saw light or stars though they were often temporarily blind A study of visual phenomena associated with the later stages of such wounds is more instructive

One of my patients was wounded over the pole of the right occipital lobe in 1916, as a result of which he has still a small left-sided paracentral scotoma, chiefly in the upper quadrants Since being wounded he has been subject to fits, all of which begin with flashes of light to the left of his fixation-point, apparently just outside the scotoma He describes the flashes as "shell bursts" or "balls of fire but redder than any fire," which dance about to his left, then vision to his left becomes hazy, everything seems to be receding into the distance, his left arm and later his left leg become numb and he loses consciousness On one occasion on which I was able to examine him immediately after a seizure there was for a time a left-sided hemianopia

In another man with a similar wound near the right occipital pole, the fits began with the appearance of very "bright lights of all colours" in the left of the point on which the eyes were directed They grew brighter and brighter until he lost consciousness He exteriorised these visual sensations so vividly that on a few occasions he assaulted nurses who came to his assistance, as he thought they were "flashing those lights in front of my eyes"

In a third man, who had a piece of metal embedded near the anterior end of the left calcarine fissure, the epileptiform attacks commenced with the appearance of a dull black patch which he referred to the lower part of the outer canthus of his right eye Next flashes of lightning appeared in the same place and often persisted for 10–15 minutes Simultaneously, or somewhat later in the severer attacks, his right limb became numb and powerless and he lost consciousness

I have observed a large number of similar cases, in all of which the traumatic lesion lay near and frequently injured the calcarine visual area There seems, therefore, little doubt that these relatively simple and crude visual phenomena must be attributed to a discharge spreading over the receptive visual cortex I have never seen them occur as primary phenomena in epileptiform seizures due to injury or disease of other portions of the brain They may obviously result from discharges spreading back to the occipital cortex from the parietal or temporal lobes, but then they are preceded by motor or sensory auræ

It is probable that purely negative phenomena may occur in patients subject to visual epilepsy, one man with a gunshot wound of the right occipital region informed me that while reading he sometimes lost his sight to his left side, and another, also with a right occipital injury, that while in a cinema he suddenly became unable to see to his left, but I have not had an opportunity of examining a patient during temporary primary hemianopia

It is evident that irritation of the primary visual receptive area in the cortex produces symptoms closely analogous to those that result from similar excitations of the motor and sensory cortex—that is simple phenomena which are projected into and often move through space, followed by loss of vision in the area they occupied, and sometimes replaced by a primary loss of vision

Complex or highly organised subjective visual sensations do not result directly from lesions of the occipital cortex Such have however, been described in association with local cerebral lesions and repeatedly with such as had involved part of the cerebral visual system These are not, however comparable to the phenomena which we are considering here In some cases of hemianopia due to destruction of either the optic radiations or of the visual cortex, the patient states that he "sees something present in the blind area of the field, some describe it as a "something" there, others state it resembles a familiar object, usually of simple form, in other cases it is identified with a human figure, but its presentation is always vague and its character so indefinite that it cannot be distinguished as anything known Whatever form it takes, it *generally persists a long time usually* until the patient's attention is diverted These visual appearances are similar in nature to the hallucinations or imaginary visions which are not uncommon in the blind, especially those who have lost sight from disease of the optic nerves or tracts

More complicated subjective visual phenomena are frequently associated, as Hughlings Jackson originally pointed out, with local lesions in the neighbourhood of the uncus of the temporal lobe, but they are different in origin and nature to those we are studying I refer to them here only for purpose of contrast

These uncinate epileptic seizures frequently begin with subjective smells and tastes which are almost invariably of an unpleasant, usually of an extremely disagreeable, character, often there is, too, an epigastric sensation which may amount to actual nausea Then comes that peculiar mental state which Jackson called the "dreamy state" or "intellectual aura," *characterised by a feeling of* unreality of the present or of familiarity with the events of the moment as though they had been experienced before Often visions which the patient associates with the past come up A patient whom I had under observation always saw, in this stage a woman with a red cloak approaching nearer and nearer until, as the spectre reached her, she lost consciousness In other cases, the vision may be a scene tinted with a tone of familiarity, a building or a similar object In such cases the visual hallucinations, for to these the term hallucination can be applied, is only part of the intellectual aura of Jackson and is obviously the result of more complicated cerebral and psychological processes than the perception and projection of lights or colours

It is difficult to suggest why it is only from the temporal lobe, and generally only by lesions involving directly or indirectly the olfactory (and probably the gustatory) centre in the uncinate gyrus, that these complex mental states with highly organised visual phenomena are excited, possibly the explanation may be found in the fact that this region of the brain, which belongs to the rhinencephalon, represents the phylogenetically *oldest* portion of the cerebral cortex, and that even in man it still serves as a storehouse of simple memories and associations

Auditory Epilepsy.

The only other sense discharges excited by focal irritation of the brain that may usher in or even constitute an epileptic attack are subjective sounds or other auditory phenomena These are relatively rare and in nature less striking and characteristic than the motor, sensory, visual, and even than the olfactory and gustatory phenomena, to which I have already referred

I have met some interesting examples of this phenomenon A man, who during the war had received a penetrating gunshot wound in the right side of his head, later became subject to epileptic fits Most of these began with a sound like the ringing of a bell in or outside his left ear This noise became louder and louder until he lost consciousness In many of the later attacks, however, there was no loss of consciousness, and only local convulsions beginning with turning of the head and eyes towards the left I have never the opportunity of observing one of these seizures or examining him immediately after one, but the patient, who was an intelligent man, never noticed any loss or disturbance of hearing at the end of either a local or general attack The explanation is that neither cortical auditory area receives exclusively impressions from either ear, and therefore even complete functional paralysis of one does not produce any obvious defect of hearing in either ear.

These various epileptiform phenomena, all of which are characterised by continuous (tonic) and intermittent (clonic) manifestations which spread over the body, or are projected through space in a manner determined by the anatomical representation in the brain of the parts of the body and of relative space around it, result directly from what we may still, following Hughlings Jackson, call a " discharge " in the cerebral cortex Both clinical and experimental evidence is strongly in favour of this view ; physiological experiments show that though movements and probably sensations may be excited by electrical and other forms of stimulation of the white matter, these do not outlast the stimulation, they do not tend to spread and are not followed by any evidence of exhaustion or facilitation, all of which may be seen on stimulation of the cortex, and observed in epileptiform attacks arising from it

Two factors are necessary that attacks may occur ; an adequate state of excitability of the cortex and a structural lesion or state of functional instability which predisposes to a discharge in it Jackson regarded the discharging lesion as a fulminate which may explode neighbouring or associated healthy nervous mechanisms The actual nature of the lesion has probably little influence, though one that increases slowly in extent and severity is usually more effective than one that is stationary. It is not necessary that the lesion actually involves the region of the cortex in which the discharge is excited , it is frequently effective if it merely lies in its proximity When, however, it does extend into the discharging cortex, it is essential that it does not destroy its anatomical integrity, or interfere seriously with its functional capacity

It is probable that the presence of a lesion in the neighbourhood of the cortex raises its excitability in addition to acting as a discharging focus , it may be, in fact, wholly to this raised excitability and instability that the discharges are due, for it has been shown experimentally that if in animals a part of the motor cortex is damaged by incisions, corrosive fluids, or other means, convulsions may be excited from it or its neighbourhood by much smaller doses of strychnine and cocaine than are effective in the intact animal The level of cortical excitability may be of course influenced by other factors , we know, for instance, that alcohol, excitement, and in ordinary epilepsy possibly disturbances in the endocrine functions, increase the liability to attacks, while it can be diminished by certain drugs, as bromides

Influence of Peripheral Stimuli

An interesting matter that has received little attention is the influence of peripheral stimuli in exciting local attacks in that part of the body that is stimulated Many patients subject to Jacksonian epilepsy commencing in one hand, for instance, are careful to shield this hand from injury or stimulation of any kind, and they frequently attribute a seizure to some irritation or accident to it Thus evidence may not carry much weight, since it is the way of all patients to find an obvious explanation of their symptoms Some years ago, when investigating with Sir H Head the disturbances of sensation produced by cortical lesions, I was struck by the fact that during the prolonged examination of tactile and other forms of cutaneous sensibility over one hand, Jacksonian spasms occasionally commenced in this part in patients with cortical lesions not subject to frequent attacks Some patients recognising this were reluctant to submit to examination. I have frequently repeated this experiment since, and have been able, in certain cases, to induce typical local spasms in a hand or foot by repeated stimulation of it The most effective means is usually a long or regular series of tactile contacts with a wisp of cotton-wool, a camel's hair brush, or von Frey's hairs The attack induced usually commences with a few clonic movements, or a curious purposeless restlessness, and may extend no further if the stimulation is stopped ; sometimes, however, they spread and may involve the whole of one side of the body These movements start almost invariably in the part that is being tested ; I have seen them more frequently elicited in the hand and fingers than elsewhere, probably because it is here that sensation is usually subjected to the most searching examination As long ago as 1863 Hughlings Jackson described a case in which touching the thumb would sometimes bring on a fit, and later another case in which seizures followed testing for ankle-clonus He also cites an observation of Brissaud's that percussion of the patellar tendon excited local epileptic attacks

In a few cases no movements occur, at least as primary phenomena, but the patient complains that the stimuli employed have suddenly excited in the area tested a numbness, a tingling, or other paræsthesiæ, apparently identical with those that occur in sensory epilepsy. These may remain local or spread, and may or may not be followed by motor spasms I have seen one patient at least whose hand after a prolonged examination of sensation suddenly " went dead " and became so anæsthetic that further testing of sensation was impossible It is probable that the sudden variations in sensibility occasionally met during the examination of sensation in patients with lesions of a parietal lobe are due to a palsy of cortical function brought about by stimulation

I have also seen a few men with gunshot wounds in the neighbourhood of the motor cortex who asserted that long continued use of the hand of the side opposite to that on which the wound was tended to excite local spasms or seizures beginning in that hand. We have some experimental confirmation of this, for Sauerbruch found that if the paw of a monkey was flexed and extended passively.for a long period local spasms were excited in it by the injection of a dose of cocaine so small that it had no effect if the animal had been at rest, or if its paw had not been submitted to passive movement

Some men subject to epileptiform attacks commencing with visual phenomena owing to gunshot wounds of the occipital region have told me that bright lights, cinema exhibitions, and other strong retinal stimuli tend to bring on attacks Auditory stimuli may also excite attacks which commence with auditory auræ. A man who consulted me some time ago had been subject since an accident to his head to epileptic seizures which commence with a sound like the note of a high-pitched bell in his left ear ; he is convinced that any loud noise may bring on an attack, and has consequently given up his profession and retired to a quiet country place, where the seizures have been much less common And some months ago I saw in the National Hospital a woman, under the care of my colleague Dr. Risien Russell, who was subject to left-sided motor and sensory attacks, some of which commenced with a noise or a musical tune In her case, too, epileptiform attacks were brought on by loud noises Later a tumour was removed from her right temporal lobe

There is therefore a certain amount of evidence that the peripheral stimulation of a limb which is subject to motor or sensory epilepsy, or of a sense organ to which analogous phenomena are referred, may excite epileptic symptoms if the corresponding part of the cortex is in an unstable state The explanation is attacks ceased, then disappearing gradually from the centre towards the periphery

In all attacks the eyes deviated towards the left and the head turned in the same direction as soon as the visual spectra appeared This deviation of the eyes and head was at first tonic but later became clonic, it could be controlled to some extent by the patient In some of the attacks at least it was probably secondary to the visual spectra, the gaze being directed reflexly towards the point in space to which the spectra were projected This man had in all probability a cerebral tumour, but its position in the brain was not determined Gowers assumed that the symptoms were due to a lesion in the neighbourhood of the angular gyrus

Gowers records in the same lecture another case, that of a girl, aged 9, who was under my observation for some years She had been, since receiving an injury to her head at the age of 3½ years, subject to right-sided epileptiform attacks, most of which began with the appearance of a bright light in the right halves of her visual fields, which she spoke of as "twinkles," probably because it scintillated Frequently there were colours in it As soon as it appeared she invariably brought her hand to the outer side of her right eye "to rub it away" Her head and eyes turned slowly to the right, she lost consciousness, and developed tonic and clonic spasms in her right limbs On regaining consciousness there was a defect of vision in each eye to the right of the fixation-point, occasionally a complete hemianopia which cleared up quickly Mr Sargent discovered a cyst, probably the result of a traumatic hæmorrhage, in the left angular gyrus, but it is possible that there were other lesions nearer the calcarine area

Similar attacks of visual epilepsy have been frequently observed in men who had received gunshot wounds in the occipital region Several such cases informed me that some time after the infliction of the wound, or on regaining consciousness after it, they saw light or stars though they were often temporarily blind A study of visual phenomena associated with the later stages of such wounds is more instructive

One of my patients was wounded over the pole of the right occipital lobe in 1916, as a result of which he has still a small left-sided paracentral scotoma, chiefly in the upper quadrants Since being wounded he has been subject to fits, all of which begin with flashes of light to the left of his fixation-point, apparently just outside the scotoma He describes the flashes as "shell bursts" or "balls of fire but redder than any fire," which dance about to his left, then vision to his left becomes hazy, everything seems to be receding into the distance, his left arm and later his left leg become numb and he loses consciousness On one occasion on which I was able to examine him immediately after a seizure there was for a time a left-sided hemianopia

In another man with a similar wound near the right occipital pole, the fits began with the appearance of very "bright lights of all colours" in the left of the point on which the eyes were directed They grew brighter and brighter until he lost consciousness He exteriorised these visual sensations so vividly that on a few occasions he assaulted nurses who came to his assistance, as he thought they were "flashing those lights in front of my eyes"

In a third man, who had a piece of metal embedded near the anterior end of the left calcarine fissure, the epileptiform attacks commenced with the appearance of a dull black patch which he referred to the lower part of the outer canthus of his right eye Next flashes of lightning appeared in the same place and often persisted for 10–15 minutes Simultaneously, or somewhat later in the severer attacks, his right limb became numb and powerless and he lost consciousness

I have observed a large number of similar cases, in all of which the traumatic lesion lay near and frequently injured the calcarine visual area There seems, therefore, little doubt that these relatively simple and crude visual phenomena must be attributed to a discharge spreading over the receptive visual cortex I have never seen them occur as primary phenomena in epileptiform seizures due to injury or disease of other portions of the brain They may obviously result from discharges spreading back to the occipital cortex from the parietal or temporal lobes, but then they are preceded by motor or sensory auræ.

It is probable that purely negative phenomena may occur in patients subject to visual epilepsy, one man with a gunshot wound of the right occipital region informed me that while reading he sometimes lost his sight to his left side, and another, also with a right occipital injury, that while in a cinema he suddenly became unable to see to his left, but I have not had an opportunity of examining a patient during temporary primary hemianopia

It is evident that irritation of the primary visual receptive area in the cortex produces symptoms closely analogous to those that result from similar excitations of the motor and sensory cortex—that is simple phenomena which are projected into and often move through space, followed by loss of vision in the area they occupied, and sometimes replaced by a primary loss of vision

Complex or highly organised subjective visual sensations do not result directly from lesions of the occipital cortex Such have however, been described in association with local cerebral lesions and repeatedly with such as had involved part of the cerebral visual system These are not, however comparable to the phenomena which we are considering here In some cases of hemianopia due to destruction of either the optic radiations or of the visual cortex, the patient states that he "sees something present in the blind area of the field some describe it as a "something" there, others state it resembles a familiar object, usually of simple form, in other cases it is identified with a human figure, but its presentation is always vague and its character so indefinite that it cannot be distinguished as anything known Whatever form it takes, it generally persists a long time usually until the patient's attention is diverted These visual appearances are similar in nature to the hallucinations or imaginary visions which are not uncommon in the blind, especially those who have lost sight from disease of the optic nerves or tracts

More complicated subjective visual phenomena are frequently associated, as Hughlings Jackson originally pointed out, with local lesions in the neighbourhood of the uncus of the temporal lobe, but they are different in origin and nature to those we are studying I refer to them here only for purpose of contrast

These uncinate epileptic seizures frequently begin with subjective smells and tastes, which are almost invariably of an unpleasant, usually of an extremely disagreeable, character, often there is, too, an epigastric sensation which may amount to actual nausea Then comes that peculiar mental state which Jackson called the "dreamy state" or "intellectual aura," characterised by a feeling of unreality of the present or of familiarity with the events of the moment as though they had been experienced before Often visions which the patient associates with the past come up A patient whom I had under observation always saw, in this stage a woman with a red cloak approaching nearer and nearer until, as the spectre reached her, she lost consciousness In other cases, the vision may be a scene tinted with a tone of familiarity, a building or a similar object In such cases the visual hallucinations, for to these the term hallucination can be applied, is only part of the intellectual aura of Jackson and is obviously the result of more complicated cerebral and psychological processes than the perception and projection of lights or colours

It is difficult to suggest why it is only from the temporal lobe, and generally only by lesions involving directly or indirectly the olfactory (and probably the gustatory) centre in the uncinate gyrus, that these complex mental states with highly organised visual phenomena are excited, possibly the explanation may be found in the fact that this region of the brain, which belongs to the rhinencephalon, represents the phylogenetically oldest portion of the cerebral cortex, and that even in man it still serves as a storehouse of simple memories and associations

AUDITORY EPILEPSY

The only other sense discharges excited by focal irritation of the brain that may usher in or even constitute an epileptic attack are subjective sounds or other auditory phenomena These are relatively rare and in nature less striking and characteristic than the motor, sensory, visual, and even than the olfactory and gustatory phenomena, to which I have already referred

I have met some interesting examples of this phenomenon A man, who during the war had received a penetrating gunshot wound in the right side of his head, later became subject to epileptic fits Most of these began with a sound like the ringing of a bell in or outside his left ear. This noise became louder and louder until he lost consciousness In many of the later attacks, however, there was no loss of consciousness and only local convulsions beginning with turning of the head and eyes towards the left I have never the opportunity of observing one of these seizures or examining him immediately after one, but the patient, who was an intelligent man, never noticed any loss or disturbance of hearing at the end of either a local or general attack The explanation is that neither cortical auditory area receives exclusively impressions from either ear, and therefore even complete functional paralysis of one does not produce any obvious defect of hearing in either ear.

These various epileptiform phenomena, all of which are characterised by continuous (tonic) and intermittent (clonic) manifestations which spread over the body, or are projected through space in a manner determined by the anatomical representation in the brain of the parts of the body and of relative space around it, result directly from what we may still, following Hughlings Jackson, call a "discharge" in the cerebral cortex Both clinical and experimental evidence is strongly in favour of this view, physiological experiments show that though movements and probably sensations may be excited by electrical and other forms of stimulation of the white matter, these do not outlast the stimulation, they do not tend to spread and are not followed by any evidence of exhaustion or facilitation, all of which may be seen on stimulation of the cortex, and observed in epileptiform attacks arising from it

Two factors are necessary that attacks may occur; an adequate state of excitability of the cortex and a structural lesion or state of functional instability which predisposes to a discharge in it Jackson regarded the discharging lesion as a fulminate which may explode neighbouring or associated healthy nervous mechanisms The actual nature of the lesion has probably little influence, though one that increases slowly in extent and severity is usually more effective than one that is stationary. It is not necessary that the lesion actually involves the region of the cortex in which the discharge is excited, it is frequently effective if it merely lies in its proximity When, however, it does extend into the discharging cortex, it is essential that it does not destroy its anatomical integrity, or interfere seriously with its functional capacity

It is probable that the presence of a lesion in the neighbourhood of the cortex raises its excitability in addition to acting as a discharging focus, it may be, in fact, wholly to this raised excitability and instability that the discharges are due, for it has been shown experimentally that if in animals a part of the motor cortex is damaged by incisions, corrosive fluids, or other means, convulsions may be excited from it or its neighbourhood by much smaller doses of strychnine and cocaine than are effective in the intact animal The level of cortical excitability may be of course influenced by other factors, we know, for instance, that alcohol, excitement, and in ordinary epilepsy possibly disturbances in the endocrine functions, increase the liability to attacks, while it can be diminished by certain drugs, as bromides

INFLUENCE OF PERIPHERAL STIMULI

An interesting matter that has received little attention is the influence of peripheral stimuli in exciting local attacks in that part of the body that is stimulated Many patients subject to Jacksonian epilepsy commencing in one hand for instance, are careful to shield this hand from injury or stimulation of any kind, and they frequently attribute a seizure to some irritation or accident to it Thus evidence may not carry much weight, since it is the way of all patients to find an obvious explanation of their symptoms Some years ago, when investigating with Sir H Head the disturbances of sensation produced by cortical lesions, I was struck by the fact that during the prolonged examination of tactile and other forms of cutaneous sensibility over one hand, Jacksonian spasms occasionally commenced in this part in patients with cortical lesions not subject to frequent attacks Some patients recognising this were reluctant to submit to examination. I have frequently repeated this experiment since, and have been able, in certain cases, to induce typical local spasms in a hand or foot by repeated stimulation of it The most effective means is usually a long or regular series of tactile contacts with a wisp of cotton-wool, a camel's hair brush, or von Frey's hairs The attack induced usually commences with a few clonic movements, or a curious purposeless restlessness, and may extend no further if the stimulation is stopped; sometimes, however, they spread and may involve the whole of one side of the body. These movements start almost invariably in the part that is being tested; I have seen them more frequently elicited in the hand and fingers than elsewhere, probably because it is here that sensation is usually subjected to the most searching examination. As long ago as 1863 Hughlings Jackson described a case in which touching the thumb would sometimes bring on a fit, and later another case in which seizures followed testing for ankle-clonus He also cites an observation of Brissaud's that percussion of the patellar tendon excited local epileptic attacks

In a few cases no movements occur, at least as primary phenomena, but the patient complains that the stimuli employed have suddenly excited in the area tested a numbness, a tingling or other paræsthesiæ, apparently identical with those that occur in sensory epilepsy These may remain local or spread, and may or may not be followed by motor spasms. I have seen one patient at least whose hand after a prolonged examination of sensation suddenly "went dead" and became so anæsthetic that further testing of sensation was impossible It is probable that the sudden variations in sensibility occasionally met during the examination of sensation in patients with lesions of a parietal lobe are due to a palsy of cortical function brought about by stimulation.

I have also seen a few men with gunshot wounds in the neighbourhood of the motor cortex who asserted that long continued use of the hand of the side opposite to that on which the wound was tended to excite local spasms or seizures beginning in that hand. We have some experimental confirmation of this, for Sauerbruch found that if the paw of a monkey was flexed and extended passively for a long period local spasms were excited in it by the injection of a dose of cocaine so small that it had no effect if the animal had been at rest, or if its paw had not been submitted to passive movement

Some men subject to epileptiform attacks commencing with visual phenomena owing to gunshot wounds of the occipital region have told me that bright lights, cinema exhibitions, and other strong retinal stimuli tend to bring on attacks Auditory stimuli may also excite attacks which commence with auditory auræ A man who consulted me some time ago had been subject since an accident to his head to epileptic seizures which commence with a sound like the note of a high-pitched bell in his left ear; he is convinced that any loud noise may bring on an attack, and has consequently given up his profession and retired to a quiet country place where the seizures have been much less common And some months ago I saw in the National Hospital a woman, under the care of my colleague Dr Risien Russell, who was subject to left-sided motor and sensory attacks, some of which commenced with a noise or a musical tune. In her case, too, epileptiform attacks were brought on by loud noises Later a tumour was removed from her right temporal lobe

There is therefore a certain amount of evidence that the peripheral stimulation of a limb which is subject to motor or sensory epilepsy, or of a sense organ to which analogous phenomena are referred, may excite epileptic symptoms if the corresponding part of the cortex is in an unstable state. The explanation is probably that the inflow of a large mass of sensory impressions to the cortex raises its excitability and consequently makes it more liable to discharge if it is in an instable state owing to the existence of injury or disease Possibly this enhanced excitability of the cortex by peripheral stimuli in abnormal amount may explain the "reflex epilepsy" of which Brown-Sequard and his successors wrote so much, but it must be admitted that the justification of this term is seriously questioned to-day

Another interesting fact is that local spasms of cortical origin can be sometimes arrested by various devices applied to the part where they commence Many patients subject to Jacksonian epilepsy assert that they can prevent a certain number of their attacks from spreading by various means; since the days of Galen some have relied on a ligature around the limb which can be pulled tightly when the attack begins, others find that checking the spasms passively by seizing the part convulsed is more effective, others attempt to arrest the convulsions by strong volitional innervation of the antagonistic muscles, while some resort to vigorous sensory stimulation, as slapping the part with a hand or plunging it into cold water How these measures act it is difficult to say; it may be that they excite an inhibition of those portions of the cortex at and around the point where the discharge is commencing There is, however, no doubt that portions of the cerebral cortex from which epileptic phenomena can be elicited may be so influenced by stimulation of corresponding parts of the periphery of the body that discharges result, or on the other hand that discharges commencing are checked

These phenomena of local epilepsy which result from excitation, exhaustion, and inhibition of an area of cortex in a state of functional instability belong to a relatively simple physiological level But they are all closely related to features of ordinary epilepsy, in which factors of the same order acting at a higher physiological plane where discharges of positive and negative nature may spread more quickly and more widely help to explain the origin and many of the characters of the seizures

PSYCHOGENIC ASTHMA

A RECORD OF TWO CASES

By E B STRAUSS, M B Oxf, M R C P Lond,
MEDICAL REGISTRAR TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE

There has never been unanimity of opinion regarding the pathogenesis of asthma Until recent years the condition was commonly regarded as a "reflex neurosis," and radical therapy consisted in the search for, and removal of, obstructions to respiration and other foci of irritation To-day it is usual to regard asthma as an expression of protein hypersensitivity, and it is grouped in text-books with hay-fever, urticaria, and other anaphylactic phenomena The protein-idiosyncrasy theory of asthma is held so strongly by one authority that he is unwilling to accord ætiological significance to any other factor

The two cases, sent to me by Sir Charlton Briscoe, which are briefly described, here suggest that such an exclusive view might be modified The cases are quoted as exceptional, and their citation should not imply that the writer regards asthma as a pure psychoneurosis Asthmatic attacks are clearly brought about through the agency of the vegetative nervous system In many cases the disturbance is initiated by a biochemical stimulus, in others, it is suggested, the disturbance is to be sought for at the psychological level Similarly, recent work has shown that attacks which are clinically indistinguishable from so-called *true* epileptic fits can be the expression of mental conflict Furthermore, it is a commonplace of clinical observation that even in those cases of asthma in which protein idiosyncrasy can be clearly demonstrated mental stress can precipitate the attacks With regard to the two cases here described, it is of interest to note that two different forms of technique were employed in their psychological investigation, neither of which involved psycho-analysis in the Freudian sense, and that in neither case was the psychogenesis traced to the sex-instinct

Case 1 —A boy, aged 12 years, who had suffered from asthma preceded by feelings of restlessness for nine years During the period October, 1921, to January, 1922, which was spent in hospital, he had had no attacks and had put on weight, but he had at once relapsed on returning home Physical examination revealed nothing abnormal. It was difficult to win the boy's confidence, and psychotherapy met at the beginning with considerable suspicion and resentment Hypno-analysis was the psychotherapeutic method chosen in this case Although resistant at first, he proved to be an excellent hypnotic subject, and was eventually able under hypnosis to recall, and in fact to re-experience, his past birthdays as far back as his second birthday His manner and vocabulary were always appropriate to the period of life under recollection

The investigation showed that the asthmatic attacks centred round the emotion of fear and the idea of suffocation Under deep hypnosis the following repressed traumatic memories were vividly recalled, and by suggestion subsequently restored to consciousness He remembered that at the age of two his nurse used to silence his cries by stuffing pieces of rag into his mouth She told him that if he were a naughty boy a man would come and take him away in a sack She used to beat him with a broom and sometimes locked him in a dark coal-cellar, which was stuffy and full of cobwebs Another incident recalled under hypnosis, which occurred at the age of two, but which seemed to have little direct bearing on his asthma, was falling off a fence and being picked up by his mother who thought he was dead This story was corroborated by his mother The relation of these experiences was accompanied by much pantomime and a considerable display of emotion Upon their restoration to consciousness asthmatic attacks ceased to recur I saw him on six occasions, with intervals of one week between periods of treatment, which lasted for about an hour

Case 2 —A woman, aged 31 years, a school-teacher, had suffered from recurrent bronchitis since the age of 9 Asthma was diagnosed by her doctor at the age of 17 Her severe attacks usually occurred in the summer months, but she was subject to bouts of dyspnœa whenever she was at home For one period of two years' duration she enjoyed a complete remission from asthma, this period corresponded with her regular attendance at the confessional (she was an Anglo-Catholic, and had found a sympathetic confessor for the time being)

Her attacks occurred at night and were invariably preceded by the following dream "I find myself by the side of a brook, quite close to my home The brook overflows and engulfs me When the water reaches my neck, I awaken into an asthmatic attack" She had dyspnœa for about three hours following the attack, but usually managed to get to sleep again at about 5 A M Her attacks, which were typical attacks of spasmodic asthma, were sometimes followed by bronchitis, in any case she usually had to stay away from school for about three weeks suffering from cough with copious yellow expectoration She remembered having at the age of three fallen into a stream from which she was speedily rescued, and she was subsequently put to bed for the rest of the day She occasionally had claustrophobiac dreams, and at times suffered from slight claustrophobia in waking life Temperamentally she is a cyclothyme, "always either up in the clouds or down in the dumps"

Physical examination showed a left-sided deflection of her nasal septum and large tonsils Her respiratory movements were of the thoracic type, with deficient use of the diaphragm in inspiration Otherwise there were no physical signs In the course of the "therapeutic conversation" the latent meaning of her recurrent dream became clear The interpretation, which she accepted with conviction, provided a satisfactory explanation not only of her dream but also of the asthmatic attacks It is important to stress the fact that the revealed conflict for which the asthmatic attacks sought to provide a solution in symbolic form was a current one and unconnected with the patient's sexual life The writer saw her on only one occasion for about one hour in February, 1925 Since her "analysis" she has had no return of asthma according to her letter of Feb 27th, 1927

These two cases show that it is always worth while to consider the psychological side of asthma In Case 1 there was no obvious cause for the condition In Case 2 there were three factors (*a*) bronchitis, (*b*) enlarged tonsils, (*c*) a deflected nasal septum, which might have been regarded as causal, and to the elimination of which treatment might have been exclusively—and fruitlessly—directed

TUBERCULOSIS OF THE LARYNX AND ARTIFICIAL PNEUMOTHORAX.

NINE CASES: COMPLETE HEALING IN SIX

(From King Edward VII Sanatorium, Midhurst)

BY SIR STCLAIR THOMSON, M D,
HONORARY LARYNGOLOGIST,
AND
RICHARD R TRAIL, M D,
RESIDENT MEDICAL SUPERINTENDENT

Laryngeal Tuberculosis and General Prognosis

IT has long been recognised that secondary infection of the larynx is more frequent in advanced cases of pulmonary tuberculosis When it occurs in earlier cases, or in those with limited chest lesions, experience teaches that this complication generally indicates either a severe type of infection, or a lessened degree of resistance, or both There is rarely an exception to this principle, particularly if tubercle bacilli are present and persistent in the sputum In "closed" cases—i e, from free T B—on the other hand, the laryngeal lesion is always less alarming and the prospect is less dark

The influence of a laryngeal lesion in rendering the general prognosis more gloomy has been demonstrated by previous investigations made in this sanatorium [1] Briefly stated, these showed that 75 per cent of all laryngeal cases seen here were dead within five years, and that of three patients with a throat complication two were dead within a period when, after the same lapse of time in purely pulmonary cases, two out of three patients would still be alive

Local Treatment.

At the present time, after 16 years' experience, the chief local measures on which we have been led to rely are voice rest and the galvano-cautery The first is always beneficial But strict silence can only be counted on for complete cicatrisation in a limited number of cases Out of 477 laryngeal cases it was only thought worth insisting on in 67 cases Of these 23 were cured (=34 3 per cent) So, also, the cautery was only deemed suitable in 74 cases, though it effected a cure in no less than 46 of them (=62 1 per cent) Both methods, separately or combined, take many months, and though they may fulfil the Hippocratic principle of healing *tuto*, they can neither of them claim to be *cito et jucunde*

Artificial Pneumothorax.

We therefore welcome any further measure which promises to meet these two desirabilities Artificial pneumothorax (A P T), in the treatment of suitable cases of pulmonary tuberculosis, has become a well-established measure, with daily increasing experience as to its indications, limitations, and results

Some References to the Literature

The published references concerning laryngeal tuberculosis and pneumothorax are not numerous This may be because the regular examination of the larynx in all chest cases has not yet become an established routine, or because, as above-mentioned, a laryngeal lesion always means a more severe infection and hence the number of such cases (pulmonary and laryngeal) suitable for treatment by artificial pneumothorax cannot be large It will also be realised that such cases cannot be very numerous, as they are restricted to those with a unilateral lung lesion, or, at most, with only a trifling invasion of the other side Riviere says that laryngeal tuberculosis is no contra-indication unless far advanced, and even then a doubtful one [2] Burrell agrees that "tuberculous laryngitis is no contra-indication and is usually improved by the treatment" [3] Dumarest and Brette have noticed that the laryngeal condition is never aggravated by this treatment, that it is generally improved, and that, in any case, it renders the larynx more favourable for local treatment [4] The experience of Swezey and Schoubar is that only acute tuberculous lesions in the larynx contra-indicate pneumothorax treatment [5] Legourd has had experience of 56 patients with active laryngeal tubercle in 300 cases treated with pneumothorax He considers it a precious addition to our treatment; never regards it as a contra-indication; and, on the contrary, thinks that the laryngeal lesion should urge us to lose no time but rather to employ it promptly in suitable cases [6]

Clinical Records

The following cases have been long and carefully observed In all of them tubercle bacilli were present, the laryngeal lesions were definite and progressive, in five of them rapid healing followed the collapse of one lung; in the sixth case the addition of local treatment with the galvano-cautery secured cicatrisation

CASE 1 *Male, aged 23, both cords bright-red, abraded, and ulcerated Improvement within a month of A P T, and quite healed within two months*—Had been husky for two months when admitted on April 4th, 1926, with a shallow ulcer over each vocal process He had a very active lesion of the left lung, his temperature (rectal) on absolute rest ranged between 98° and 100 6°, he looked very ill, and the prognosis was regarded as grave, particularly because, in spite of rest in bed and strict silence, the laryngeal mischief increased rapidly, so that a month after admission the note was "Both cords are now bright-red, abraded on the surface and with early, superficial ulceration along the free margin of the posterior half on each side There is a deeper, triangular ulcer over each vocal process" (Fig 1) Within a month of the A P T (performed May 21st, 1926) the note made was "difficult to see any lesion" Within two months the cords were intact, but still pinkish, and the patient was allowed to talk A month later it was noted that "the cords are no longer pink, but quite white and flat There is a little *coup d'ongle* scar over the left cord posteriorly" (Fig 2)

Development of Laryngeal Tuberculosis after Admission to Sanatorium

By systematically examining the larynx of every patient admitted to Midhurst, even if he had no huskiness or any other symptom referable to that organ, it was found, during the 10 years from 1912 to 1922, that amidst 2070 who passed the first inspection as normal, six cases developed laryngeal lesions after admission Such a small proportion, once a patient is within the shelter of a sanatorium, is noteworthy Of these six cases four are dead, one is reported as very ill, and only one after ten years writes that he is alive and well

These observations (published in 1924), though few in number, prompt the hypothesis that, when laryngeal tuberculosis does develop after a patient has started sanatorium life, the prognosis is not good. It suggests a want of response to the favourable conditions, or a severe infection Hence, the following three cases are particularly interesting as showing the value of A P T, for in each of them the laryngeal mischief only started after the patient's admission to the sanatorium

CASE 2. *Male, aged 18, laryngeal tuberculosis developed in sanatorium Four months under observation and silence, without improvement Larynx healed within three months of A P T*—Admitted on Sept 30th, 1925, with early signs at both apices These remained stationary on the right side but extended on the left At the end of five months' treatment his temperature was never satisfactory His larynx was passed as "normal" on admission, but a month later, when his persistent temperature had confined him to bed, he became husky and it was found that there was inter-arytenoid crinkling and both cords were pink, abraded, and congested, particularly along their attached border (Fig 3) probably that the inflow of a large mass of sensory impressions to the cortex raises its excitability and consequently makes it more liable to discharge if it is in an instable state owing to the existence of injury or disease Possibly this enhanced excitability of the cortex by peripheral stimuli in abnormal amount may explain the "reflex epilepsy" of which Brown-Sequard and his successors wrote so much, but it must be admitted that the justification of this term is seriously questioned to-day

Another interesting fact is that local spasms of cortical origin can be sometimes arrested by various devices applied to the part where they commence. Many patients subject to Jacksonian epilepsy assert that they can prevent a certain number of their attacks from spreading by various means; since the days of Galen some have relied on a ligature around the limb which can be pulled tightly when the attack begins, others find that checking the spasms passively by seizing the part convulsed is more effective, others attempt to arrest the convulsions by strong volitional innervation of the antagonistic muscles, while some resort to vigorous sensory stimulation, as slapping the part with a hand or plunging it into cold water How these measures act it is difficult to say, it may be that they excite an inhibition of those portions of the cortex at and around the point where the discharge is commencing There is, however, no doubt that portions of the cerebral cortex from which epileptic phenomena can be elicited may be so influenced by stimulation of corresponding parts of the periphery of the body that discharges result, or on the other hand that discharges commencing are checked

These phenomena of local epilepsy which result from excitation, exhaustion, and inhibition of an area of cortex in a state of functional instability belong to a relatively simple physiological level But they are all closely related to features of ordinary epilepsy, in which factors of the same order acting at a higher physiological plane where discharges of positive and negative nature may spread more quickly and more widely help to explain the origin and many of the characters of the seizures

PSYCHOGENIC ASTHMA

A RECORD OF TWO CASES

By E B STRAUSS, M B Oxf, M R C P Lond,
MEDICAL REGISTRAR TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE

There has never been unanimity of opinion regarding the pathogenesis of asthma Until recent years the condition was commonly regarded as a "reflex neurosis," and radical therapy consisted in the search for, and removal of, obstructions to respiration and other foci of irritation To-day it is usual to regard asthma as an expression of protein hypersensitivity, and it is grouped in text-books with hay-fever, urticaria, and other anaphylactic phenomena The protein-idiosyncrasy theory of asthma is held so strongly by one authority that he is unwilling to accord ætiological significance to any other factor

The two cases, sent to me by Sir Charlton Briscoe, which are briefly described, here suggest that such an exclusive view might be modified The cases are quoted as exceptional, and their citation should not imply that the writer regards asthma as a pure psychoneurosis Asthmatic attacks are clearly brought about through the agency of the vegetative nervous system In many cases the disturbance is initiated by a biochemical stimulus, in others, it is suggested, the disturbance is to be sought for at the psychological level Similarly, recent work has shown that attacks which are clinically indistinguishable from so-called *true* epileptic fits can be the expression of mental conflict Furthermore, it is a commonplace of clinical observation that even in those cases of asthma in which protein idiosyncrasy can be clearly demonstrated mental stress can precipitate the attacks With regard to the two cases here described, it is of interest to note that two different forms of technique were employed in their psychological investigation, neither of which involved psycho-analysis in the Freudian sense, and that in neither case was the psychogenesis traced to the sex instinct

Case 1—A boy, aged 12 years, who had suffered from asthma preceded by feelings of restlessness for nine years. During the period October, 1921, to January, 1922, which was spent in hospital, he had had no attacks and had put on weight, but he had at once relapsed on returning home Physical examination revealed nothing abnormal It was difficult to win the boy's confidence, and psychotherapy met at the beginning with considerable suspicion and resentment Hypno-analysis was the psychotherapeutic method chosen in this case Although resistant at first, he proved to be an excellent hypnotic subject, and was eventually able under hypnosis to recall, and in fact to re-experience, his past birthdays as far back as his second birthday His manner and vocabulary were always appropriate to the period of life under recollection

The investigation showed that the asthmatic attacks centred round the emotion of fear and the idea of suffocation. Under deep hypnosis the following repressed traumatic memories were vividly recalled, and by suggestion subsequently restored to consciousness He remembered that at the age of two his nurse used to silence his cries by stuffing pieces of rag into his mouth. She told him that if he were a naughty boy a man would come and take him away in a sack She used to beat him with a broom and sometimes locked him in a dark coal cellar, which was stuffy and full of cobwebs Another incident recalled under hypnosis, which occurred at the age of two, but which seemed to have little direct bearing on his asthma, was falling off a fence and being picked up by his mother who thought he was dead This story was corroborated by his mother The relation of these experiences was accompanied by much pantomime and a considerable display of emotion Upon their restoration to consciousness asthmatic attacks ceased to recur I saw him on six occasions, with intervals of one week between periods of treatment, which lasted for about an hour

Case 2—A woman, aged 31 years, a school teacher, had suffered from recurrent bronchitis since the age of 9 Asthma was diagnosed by her doctor at the age of 17 Her severe attacks usually occurred in the summer months, but she was subject to bouts of dyspnœa whenever she was at home For one period of two years' duration she enjoyed a complete remission from asthma, this period corresponded with her regular attendance at the confessional (she was an Anglo-Catholic, and had found a sympathetic confessor for the time being)

Her attacks occurred at night and were invariably preceded by the following dream "I find myself by the side of a brook, quite close to my home The brook overflows and engulfs me When the water reaches my neck, I awaken into an asthmatic attack" She had dyspnœa for about three hours following the attack, but usually managed to get to sleep again at about 5 A M Her attacks, which were typical attacks of spasmodic asthma, were sometimes followed by bronchitis, in any case she usually had to stay away from school for about three weeks suffering from cough with copious yellow expectoration She remembered having at the age of three fallen into a stream from which she was speedily rescued, and she was subsequently put to bed for the rest of the day She occasionally had claustrophobic dreams, and at times suffered from slight claustrophobia in waking life Temperamentally she is a cyclothyme, "always either up in the clouds or down in the dumps"

Physical examination showed a left-sided deflection of her nasal septum and large tonsils Her respiratory movements were of the thoracic type, with deficient use of the diaphragm in inspiration Otherwise there were no physical signs In the course of the "therapeutic conversation" the latent meaning of her recurrent dream became clear The interpretation, which she accepted with conviction, provided a satisfactory explanation not only of her dream but also of the asthmatic attacks It is important to stress the fact that the revealed conflict for which the asthmatic attacks sought to provide a solution in symbolic form was a current one and unconnected with the patient's sexual life The writer saw her on only one occasion for about one hour in February, 1925 Since her "analysis" she has had no return of asthma according to her letter of Feb 27th, 1927

These two cases show that it is always worth while to consider the psychological side of asthma In Case 1 there was no obvious cause for the condition In Case 2 there were three factors (*a*) bronchitis, (*b*) enlarged tonsils; (*c*) a deflected nasal septum, which might have been regarded as causal, and to the elimination of which treatment might have been exclusively—and fruitlessly—directed

TUBERCULOSIS OF THE LARYNX AND ARTIFICIAL PNEUMOTHORAX

NINE CASES, COMPLETE HEALING IN SIX

(From King Edward VII Sanatorium, Midhurst)

BY SIR STCLAIR THOMSON, M D,
HONORARY LARYNGOLOGIST,
AND
RICHARD R TRAIL, M D,
RESIDENT MEDICAL SUPERINTENDENT

Laryngeal Tuberculosis and General Prognosis.

IT has long been recognised that secondary infection of the larynx is more frequent in advanced cases of pulmonary tuberculosis When it occurs in earlier cases, or in those with limited chest lesions, experience teaches that this complication generally indicates either a severe type of infection, or a lessened degree of resistance, or both There is rarely an exception to this principle, particularly if tubercle bacilli are present and persistent in the sputum In "closed" cases—i e, from free T B—on the other hand, the laryngeal lesion is always less alarming and the prospect is less dark

The influence of a laryngeal lesion in rendering the general prognosis more gloomy has been demonstrated by previous investigations made in this sanatorium [1] Briefly stated, these showed that 75 per cent of all laryngeal cases seen here were dead within five years, and that of three patients with a throat complication two were dead within a period when, after the same lapse of time in purely pulmonary cases, two out of three patients would still be alive

Local Treatment

At the present time, after 16 years' experience, the chief local measures on which we have been led to rely are voice rest and the galvano-cautery The first is always beneficial But strict silence can only be counted on for complete cicatrisation in a limited number of cases Out of 477 laryngeal cases it was only thought worth insisting on in 67 cases Of these 23 were cured (=34 3 per cent) So, also, the cautery was only deemed suitable in 74 cases, though it effected a cure in no less than 46 of them (=62 1 per cent) Both methods, separately or combined, take many months, and though they may fulfil the Hippocratic principle of healing *tuto*, they can neither of them claim to be *cito et jucunde*

Artificial Pneumothorax

We therefore welcome any further measure which promises to meet these two desirabilities Artificial pneumothorax (A P T), in the treatment of suitable cases of pulmonary tuberculosis, has become a well-established measure, with daily increasing experience as to its indications, limitations, and results

Some References to the Literature

The published references concerning laryngeal tuberculosis and pneumothorax are not numerous This may be because the regular examination of the larynx in all chest cases has not yet become an established routine, or because, as above-mentioned, a laryngeal lesion always means a more severe infection and hence the number of such cases (pulmonary and laryngeal) suitable for treatment by artificial pneumothorax cannot be large It will also be realised that such cases cannot be very numerous, as they are restricted to those with a unilateral lung lesion, or, at most, with only a trifling invasion of the other side Riviere says that laryngeal tuberculosis is no contra-indication unless far advanced, and even then a doubtful one [2] Burrell agrees that "tuberculous laryngitis is no contra-indication and is usually improved by the treatment" [3] Dumarest and Brette have noticed that the laryngeal condition is never aggravated by this treatment, that it is generally improved, and that, in any case, it renders the larynx more favourable for local treatment [4] The experience of Swezey and Schoubar is that only acute tuberculous lesions in the larynx contra-indicate pneumothorax treatment [5] Legourd has had experience of 56 patients with active laryngeal tubercle in 300 cases treated with pneumothorax He considers it a precious addition to our treatment; never regards it as a contra-indication; and, on the contrary, thinks that the laryngeal lesion should urge us to lose no time but rather to employ it promptly in suitable cases [6]

Clinical Records

The following cases have been long and carefully observed In all of them tubercle bacilli were present, the laryngeal lesions were definite and progressive, in five of them rapid healing followed the collapse of one lung, in the sixth case the addition of local treatment with the galvano-cautery secured cicatrisation

CASE 1 *Male, aged 23, both cords bright-red, abraded, and ulcerated Improvement within a month of A P T, and quite healed within two months*—Had been husky for two months when admitted on April 4th, 1926, with a shallow ulcer over each vocal process He had a very active lesion of the left lung, his temperature (rectal) on absolute rest ranged between 98° and 100 6°, he looked very ill, and the prognosis was regarded as grave, particularly because, in spite of rest in bed and strict silence, the laryngeal mischief increased rapidly, so that a month after admission the note was "Both cords are now bright-red, abraded on the surface and with early, superficial ulceration along the free margin of the posterior half on each side There is a deeper, triangular ulcer over each vocal process" (Fig 1) Within a month of the A P T (performed May 21st, 1926) the note made was "difficult to see any lesion" Within two months the cords were intact, but still pinkish, and the patient was allowed to talk A month later it was noted that "the cords are no longer pink, but quite white and flat There is a little *coup d'ongle* scar over the left cord posteriorly" (Fig 2)

Development of Laryngeal Tuberculosis after Admission to Sanatorium

By systematically examining the larynx of every patient admitted to Midhurst, even if he had no huskiness or any other symptom referable to that organ, it was found, during the 10 years from 1912 to 1922, that amidst 2070 who passed the first inspection as normal, six cases developed laryngeal lesions after admission Such a small proportion, once a patient is within the shelter of a sanatorium, is noteworthy Of these six cases four are dead, one is reported as very ill, and only one after ten years writes that he is alive and well

These observations (published in 1924), though few in number, prompt the hypothesis that, when laryngeal tuberculosis does develop after a patient has started sanatorium life, the prognosis is not good It suggests a want of response to the favourable conditions, or a severe infection Hence, the following three cases are particularly interesting as showing the value of A P T, for in each of them the laryngeal mischief only started after the patient's admission to the sanatorium

CASE 2 *Male, aged 18, laryngeal tuberculosis developed in sanatorium Four months under observation and silence, without improvement Larynx healed within three months of A P T*—Admitted on Sept 30th, 1925, with early signs at both apices These remained stationary on the right side but extended on the left At the end of five months' treatment his temperature was never satisfactory His larynx was passed as "normal" on admission, but a month later, when his persistent temperature had confined him to bed, he became husky and it was found that there was inter-arytenoid crinkling and both cords were pink, abraded, and congested, particularly along their attached border (Fig 3)

[5] American Rev Tuberc, 1926, xiii, 156

[6] Rev Gén de Chir et de Thérap, 1921, xxxv, 694–696

He was put on silence for seven months without improvement But a month after the A P T, while still in bed, the larynx was noted as "statu quo", a month later it was "catarrhal," and at the end of three months the note was made "quite healed, to talk"

CASE 3 *Female, aged 24, tuberculosis of larynx developed two months after admission Three months' observation, under silence, but disease extending Improvement within a month of A P T, and at the end of third month larynx healed* —Admitted on June 19th, 1924, with active signs throughout left lung, while X rays showed soft shadows under clavicle on right side Temperature within normal limits, was irregular, and she was never fit for exercise Two months after admission all the right cord and the anterior third of the left was superficially ulcerated (Fig 4) The sputum was still positive when A P T was performed on the left side on Oct 24th, 1924 A month later there was "clean ulceration of all right cord and ulceration of anterior third of left" Two months later the temperature had become normal, and the three months' silence was abandoned, for both cords were healed, although still pinkish, and the right one was irregular in all its extent Five months after the A P T the voice was restored to normal and the larynx showed no trace of disease

The next case (Case 4) is particularly interesting for the following reasons (1) it was the most extensive which, so far, has been successful, (2) it developed in the sanatorium; and (3) after six months there the patient was discharged as "worse" It was later on that A P T was carried out by Dr L Burrell, to whom we are indebted for permission to publish his record of the case

FIG 1

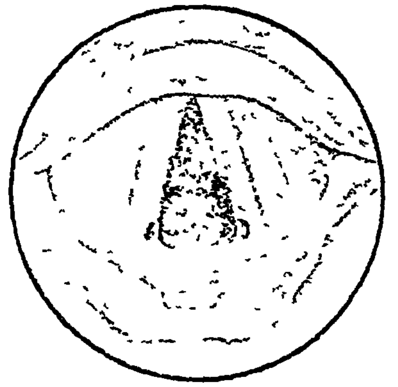

FIG 2.

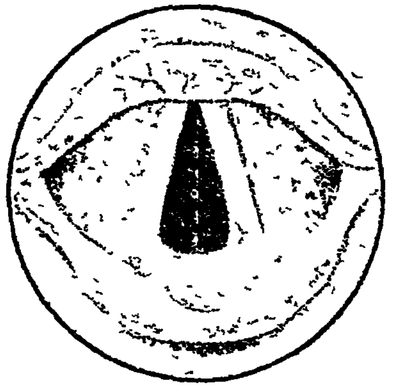

FIG. 3

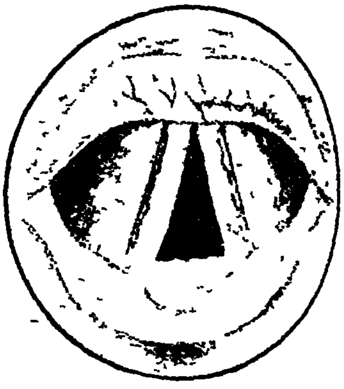

FIG 1 —The larynx in Case 1 showing abraded and ulcerated cords

FIG 2 —The larynx in Case 1, quite cicatrised three months after A P T Note the scar over left vocal process

FIG 3 —The larynx of Case 2, not improved with seven months of silence A.P T. was followed by complete healing of larynx within three months

CASE 4 *Male, aged 37, laryngeal tuberculosis developed one month after admission Extensive disease Discharged "worse" Complete healing* —Admitted on July 29th, 1922 with signs throughout the left lung and at the upper apex of the right The evening temperature (mouth) ran regularly to 99° A month afterwards he became husky and a grey-yellow, irregular ulceration was seen on the inner margin of the posterior third of each cord This extended until eight months later there was extensive ulcerating, stalactite deposit over all the interarytenoid space and ulceration of the posterior half of both cords (Fig 5) While in the sanatorium he gained 14 lb in weight, but his evening temperature (mouth) remained at 99°, the sputum was an ounce a day, and he was never fit for any exercise

He was not seen again for nearly three years—i e, not between May, 1923, and Feb 28th, 1926 It appears that after leaving the sanatorium in 1923 he passed under the care of Dr Burrell, who induced an artificial pneumothorax on April 12th, 1924 When the patient presented himself to us again on Feb 28th, 1926, he was still whispering (N B —He had never been put on strict silence as the condition was looked on as too hopeless to be worth it) We were astonished to find both cords completely healed, while a large but limited fibroid deposit, without any superficial ulceration, occupied the centre of the interarytenoid region (Fig 6) Five months later this fibrosis had diminished to an even, flat band of scar tissue across the lower part of the interarytenoid region, on a level with the cords (Fig 7) The patient had not quite succeeded in regaining the normal use of his sound cords, he had whispered so many years with his ventricular bands (*Taschenbandsprache*, as they call it in Germany) that he found it difficult to discontinue the habit! At the present moment his general medical condition is reported to be excellent, good fibrosis, no symptoms except a little cough and occasional sputum which no longer contains T.B

Artificial Pneumothorax is not Sufficient in all Cases to Effect a Cure

It will be noted that in three of these cases the healing of the laryngeal lesion was rapid—a matter of one to three months In one case (Case 4) it is difficult to say how soon the extensive disease began to heal But we must be prepared for cases in which the induction of an A P T, though helpful, is not sufficient without other (local) measures In the following case the disease in the larynx persisted for one and three quarter years after the lung had been collapsed, and in spite of prolonged silence, and then rapidly yielded to the galvano-cautery

CASE 5 *Male, aged 18, laryngeal disease present on admission, but extending after A P T No improvement at end of 21 months, in spite of silence Healed in six months with three cautery treatments* —Admitted April 6th, 1923, with T B + and an ulcer over right vocal process A P T on 24th, but, in spite of this, during the next six months the laryngeal mischief increased until there were grey, ulcerating, indolent deposits over each vocal process and the posterior half of both cords. This condition persisted throughout 1924 in spite of silence and every care on the part of the patient Consequently, galvano-cautery treatment was started in 1925, and he had three applications in January, April, and June By August the larynx was quite healed and he was allowed to talk, after more than two years of voice rest It has remained healed He has no cough and no sputum He still has refills, but his general condition is excellent, and he gains his livelihood as a book-keeper

Development of Tuberculosis of the Larynx after Admission to Sanatorium, and after Induction of Artificial Pneumothorax.

In their excellent book[7] Dumarest and Murard remark on the extreme rarity of the development of tubercle in the larynx, once the pneumothorax has been instituted A well-known American laryngologist states "I have never observed laryngeal tuberculosis develop in the course of treatment, nor did I ever see this complication occur subsequently in a patient cured or arrested by means of an artificial pneumothorax[8]

We, however, have had two cases in which this secondary infection did occur, though it was of slight extent and, in one instance, soon cleared up on the added prescription of voice rest

CASE 6 *Female, aged 20, laryngeal tuberculosis developed one month after A P T, but rapidly subsided under silence*

---

[7] Op cit

[8] Julius P Dworetzky Annals of Otol, Rhinol, and Laryng, 1926, No 1, xxv, 42.

Complete recovery—Admitted March 19th, 1923, with a normal larynx T B + A.P T on May 2nd In June huskiness called for an examination of the larynx, when the cords were found to be congested, succulent, and rounded, with a trifling interarytenoid deposit. Under strict silence this subsided in a month The larynx has remained normal since—i e, for more than three years The patient has lost all cough and sputum, general health is good, but refills are still considered advisable

FIG 4

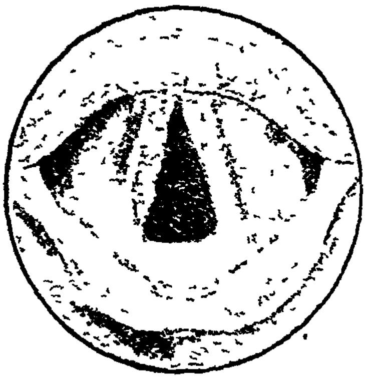

FIG 4—The larynx of Case 3 Disease extending in spite of silence Complete healing took place within three months of A P T

FIG 5

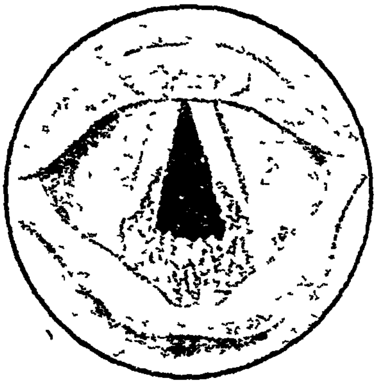

FIG 5—Extensive disease in larynx of Case 4

FIG 6

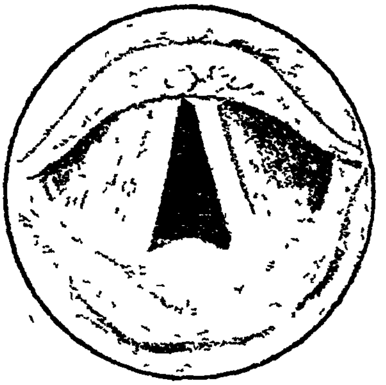

FIG 6—Larynx of Case 4 subsequent to A P T

CASE 7—We have another case still under treatment which may require the cautery. It is that of a female, aged 32, admitted on March 9th, 1926, with T B + and the larynx normal A.P T was performed on May 18th In October she became conscious of her throat and each vocal process was found to be "catarrhal and infiltrated, with small yellow spots, worse on the left" These broke down into ulcers By December (and with the addition of silence) the larynx on the right side had quite healed, but on the left side it remains in statu quo If this does not soon cicatrise spontaneously some treatment with the cautery will almost certainly ensure a cure

FIG. 7.

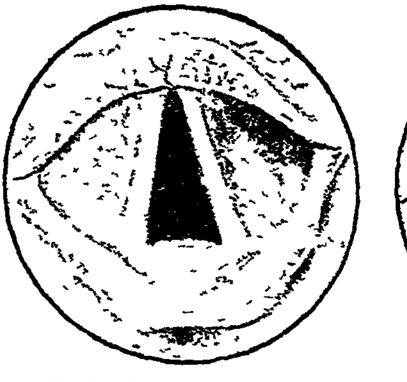

FIG 8.

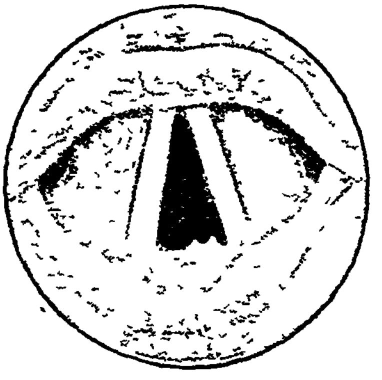

FIG 7—Larynx of Case 4, five months later to condition shown in Fig 6

FIG 8—Larynx in Case 9 This healed within two months of A.P T But collapse of lung was not complete, T B 's persisted in sputum, and larynx relapsed four months later

It will be noted that this is the second case in which tuberculosis in the larynx not only developed after admission to the sanatorium, but after the induction of artificial pneumothorax

Failure

In still a third case tuberculosis developed after admission to the sanatorium and after the performance of an A.P T, but the patient succumbed

CASE 8 *Male, aged 24, development of tuberculosis in larynx three months after admission and two months after A P T Death two years later*—Admitted Oct 7th, 1921 T B + Larynx normal A P T on Nov 30th, 1921 Two months later developed ulcerating, stalactite deposits in interarytenoid region, and an ulcerating deposit on the petiolus of the epiglottis There were never any signs of improvement He was discharged on April 20th, 1922, and died on Dec 9th, 1924

Relapse

Tuberculosis in the larynx and in the lung may recover coincidentally, or progress pari passu It has been shown that so long as the disease in the larynx is advancing, the lesion in the lung cannot become arrested* But the reverse is quite possible—i e, tuberculosis of the larynx may become healed while in the lung it continues unarrested or is even progressing We have records of many cases where tuberculosis in the larynx was healed and remained healed until the patient died, many years later from his pulmonary disease But these cases of cure in the larynx may relapse if the tuberculosis in the lung is still active Even a pneumothorax will not insure against this, as the following case will show

CASE 9 *Female, aged 24, slight laryngeal disease, but not yielding to six months' silence Healing in seven weeks after A P T Collapse of lung never complete T B 's persisted Relapse of larynx four months later*—Admitted Sept. 19th, 1925, with infiltration of upper half of right lung A month later she developed a right basal pleurisy She had been hoarse six months and had kept silence for four months before entering Midhurst with a diffused, abraded, interarytenoid deposit (Fig 8) After two more months of silence the condition remained stationary Within seven weeks of the A P T the larynx was healed and she was allowed to talk This larynx remained soundly cicatrised during the nine subsequent months we thought it wise to detain her in the sanatorium

Her stay in the sanatorium was prolonged through these months because she never had a complete collapse of the lung, it was held up at the base by the pleurisy described above Besides, she had been admitted with a negative report as regards her sputum, but we found T B present after a stay of two months, and they persisted in spite of treatment and progress However, as her general condition had improved, and the larynx was healed, she was allowed to return home after a sojourn of 11 months Four months later she again became husky, there was much laryngeal catarrh, and this time there was not only a small interarytenoid deposit but both vocal cords were pink and rounded with ulcerating deposit over each vocal process T B 's are still present, the general condition remains as satisfactory as on discharge; the left lung continues free, but the right is rather over-collapsed, possibly owing to recent refills being carried out at too frequent intervals She is shortly returning for further treatment at Midhurst

---

* StClair Thomson Op cit.

Conclusions

Cases of pulmonary tuberculosis are always rendered much more serious by the addition of a laryngeal extension

This laryngeal complication is of still worse augury if it develops after admission to a sanatorium or after induction of an artificial pneumothorax

In spite of this experience, the presence of tuberculosis in the larynx is no contra-indication to this operation On the contrary it may speedily effect a cure or render more promising the addition of galvano-cautery or other treatment

The larynx can be cured by this measure, even although bacilli may continue to be present in the sputum and mischief to be detectable in the chest

The indications for the induction of artificial pneumothorax must, primarily, be based on the pulmonary and general condition of the patient So far as the larynx is concerned the only contra-indication would be an acute, miliary invasion

THE RESULTS OF OPERATIONS FOR GASTRO-DUODENAL ULCERATION

By CHARLES A PANNETT, B.Sc, M D Lond., F R C S Eng,
PROFESSOR OF SURGERY IN THE UNIVERSITY OF LONDON, SURGEON TO ST MARY'S HOSPITAL

The reader who pursues this communication to the end may reasonably ask why such a small series has been recorded and what indeed is the worth of any deductions based upon the observation of small numbers of patients Conversant with the literature of the subject, he will have in mind the large series published in America from the Mayo Clinic, in England by such masters of surgery as Moynihan, Sherren, Paterson, and Walton, in Central Europe, where the disease has been exceptionally rife since the closing years of the Great War, by von Haberer, Finsterer, Clairmont, and others But he will also have a vivid memory of the discordant conclusions arrived at by the several observers and he will find it very difficult, by the study of these published clinical records, to formulate any line of action in the treatment of gastro duodenal ulceration which he can follow with any confidence in the rectitude of his decision It becomes, in fact, a matter which must, to a large extent, be adjudged individually by each surgeon who essays to treat such patients The experiences of operators who are in a position to practise different methods and compare them are more valuable than massed statistics in which a number of surgeons are concerned, because certain sources of error in compiling them are eliminated Though restricted numbers of patients are dealt with it is maintained that a truer estimate of the relative worth of different procedures is obtained Of 130 patients suffering from chronic gastric or duodenal ulcer (61 gastric, 69 duodenal) which have been dealt with in the Surgical Unit at St Mary's Hospital by myself, 56 only (24 gastric and 32 duodenal sufferers) have been operated upon long enough and been available for subsequent inquiry of results to afford any useful information It is of these that I wish to write

Selection of Patients Suitable for Operative Intervention

The closer acquaintance with this disease becomes the greater grows the conviction that surgery should not follow diagnosis as a routine Experience completely fails to uphold the view of some surgeons that ulcers once formed can never be induced to heal without its aid[1] I have excised segments of both stomach and duodenum with lesions indistinguishable by simple inspection from ordinary ulcers in which histological examination has shown cicatrisation to have taken place and a layer of epithelium to have spread over the surface During the periods of relief between active symptoms so characteristic of ulcer reparative activity certainly occurs, and sometimes leads to epithelialisation of the ulcer The discovery of scars in the stomach or duodenum in the post-mortem room also points in the same direction, and is not so rare an occurrence C Hart[2] found as many scars in the duodenum as actual ulcers in his series of autopsies In successive gastroscopies R Schindler[3] actually watched a gastric ulcer heal Nevertheless it is a very striking fact of pathology that, in addition to the large callous gastric or duodenal ulcers, there exist others of quite small size (sometimes in the duodenum they are mere clefts), which persist unhealed indefinitely without the aid of surgery Surgery is nearly always necessary when a Haudek diverticulum of any size can be demonstrated by X ray examination; it is certainly required when a serious haemorrhage has occurred or where the pylorus has been narrowed, but in all other cases the patient should be allowed the trial of medical measures and only when his lesion has proved intractable to these means should he be subjected to the risk of operative treatment

The Plan followed in Operating upon Ulcers

The policy adopted in dealing with these ulcers has been as follows For gastric ulcer some form of resection is considered first, and only abandoned for gastro-enterostomy when the procedure appears to be fraught with much risk or technically impossible When the ulcer is very large and its adhesions are so widespread that access to normal stomach proximal to the lesion cannot be obtained, then gastro-jejunostomy has been preferred A previous perforation or perigastric abscess may bring such conditions about Only in one case was gastro-jejunostomy done because the ulcer at the pylorus appeared to have healed leaving nothing but a scar Amongst the 61 operations for gastric ulcer, on four occasions the abdomen was closed leaving conditions within unchanged, even gastro-jejunostomy was impossible

In the case of duodenal ulcer the policy followed has been very similar, except that there have been two indications up to the present for preferring gastro jejunostomy to resection—namely, (1) doubt as to the possibility of separating the callous mass without damage to the pancreatic or bile-ducts; (2) the small soft ulcer of the anterior wall of the duodenum, where duodenectomy in its present probationary stage was considered to entail an unjustifiable risk

Amongst 61 cases of gastric ulcer a resection of the stomach was carried out in 47 (77 5 per cent), of which more than one-half (67 per cent) were cases of ulcer adherent to or penetrating the pancreas. In five of these latter the ulcer was also adherent to the liver, in one case to the spleen, and in several instances to the mesocolon A Billroth I resection with axial union was performed whenever the ulcer was not at too great a distance from the pylorus (18 times), a sleeve resection when it was situated far toward the left extremity of the lesser curvature (25 times) A Polya operation was done four times and a V-resection with gastro-jejunostomy once Gastro-jejunostomy was only done in eight cases

Amongst 69 cases of duodenal ulcer partial duodenectomy was carried out in 49 (71 per cent) Of these 33 had an ulcer on the concave pancreatic wall of the duodenum (67 3 per cent) Simple excision combined with a Finney procedure were each done once Gastro-jejunostomy was done in 18 cases (26 per cent)

When removal of the diseased part of the stomach has been done the after care is very simple There is no need for prolonged special diet The remaining stomach is smaller but healthy The patient should avoid indigestible food until it is certain that the anastomotic sites are completely healed (six weeks), after which he is able to take ordinary diet, with this reservation that too much should not be eaten at a time The stomach being smaller a feeling of distension after meals is liable to be experienced for the first few months after operation This sensation gradually disappears and after a year has gone.

Results Obtained in Gastric Ulcers.

There were two deaths amongst the 47 resections of the stomach. One of these was an operative death where the hepatic artery was accidentally ligated in a man with a callous ulcer in which cancer was developing The other man died after a Billroth I. operation on the sixth day with gangrene of the lung. I do not know whether he swallowed vomit recovering from the anæsthetic or later His stomach was somewhat dilated post mortem, a complication I have met with on two occasions after this type of gastrectomy, but one which is immediately relieved by the passage of a thin stomach-tube and aspirating the contents He had vomited after a comfortable period of three days There was a freely patent pylorus and good healing at autopsy. The mortality of gastrectomy for ulcer has therefore been 4 25 per cent

Of 20 gastric resections operated upon long enough for the after-history to be of value (18 months) 16 (80 per cent) are absolutely well The four patients still with some complaint are :—

CASE 25 —A nun of 49 operated upon May 7th, 1925 Ulcer of lesser curvature with hour-glass contraction removed by sleeve resection Now complains of a little flatulence She has no pain and eats ordinary food.

CASE 33 —A man of 37 had an ulcer of the posterior surface of the stomach near the cardiac end and adherent to the tail of the pancreas removed by sleeve resection on Sept. 23rd, 1925 For the first year after operation he complained of pain after food occasionally, but since then has been free. He has gained a stone in weight since his operation

CASE 38 —A woman of 52 had a Billroth I operation performed on June 25th, 1925. She had an early carcinoma close to the pylorus and a simple ulcer in the posterior wall of the stomach. She says she has occasional pains in the right side of her abdomen, but has no discomfort which she attributes to food.

CASE 16 —A woman of 38 had a Billroth I resection for an ulcer rather far along the lesser curvature away from the pylorus on Jan. 17th 1924 She complains of a little pain occasionally in the left side of her back. She eats ordinary food, and her weight has increased by half of what it was when she was operated upon (6 st 12 lb)

These failures are not absolute In each case the patients have received very great benefit from the operation Partial gastrectomy has therefore proved to be a most successful procedure, and sleeve resection seems as good a method as the Billroth I. or Polya operation

Gastro-jejunostomy is by general consent regarded as only of limited value as a curative operation for gastric ulcer, and rightly so, but it would be unfair not to refer to Case 30, a man of 50, who had such a large ulcer penetrating the pancreas and so many adhesions around that only an anterior gastro-jejunostomy could be carried out Fourteen months later he has no indigestion and declares himself to be in perfect health

Results Obtained in Duodenal Ulcers

Partial duodenectomy has been said to be too dangerous an operation to be considered a routine method of treatment. It is indeed a difficult and tedious procedure, but becomes more easy with increasing experience In 33 of 49 patients upon whom partial duodenectomy was performed ulcers were present on the pancreatic wall, so those cases were not selected on account of ease of performance of the operation Two patients died, one from bronchopneumonia, the other from cardiac failure 10 days after operation, a mortality of 4 per cent. This is almost exactly that of partial gastrectomy in my hands

Of 21 partial duodenectomies subsequently investigated 18 are absolutely well (85 7 per cent.) Of the three failures one complains of being full of wind after meals, but not of suffering any pain. He is very nearly quite well. The other two failures are :—

CASE 11 —A man of 37 had a resection with axial union of stomach and duodenum on April 14th, 1924 There was an ulcer on the anterior wall of the first part of the duodenum and a second on the posterior wall which had penetrated into the pancreas He now complains of some late pain after food when working, but not when he rests He eats only boiled food and says he occasionally vomits a sticky fluid

CASE 30 —A man of 28 had a similar operation performed on Nov 3rd, 1924, for an ulcer on the anterior wall of the duodenum which spread round to the back forming a stricture. This man writes very gratefully for relief of pain, but still apparently gets some of a mild character which radiates to the right shoulder He takes no special diet. He says that he is better since giving up alcohol and excessive smoking to which he was addicted

The patient whose common pancreatic and biliary ducts I accidentally injured and reported on in 1924 is now free from any abdominal trouble of any kind

During the same period that these 21 duodenectomies were done nine cases had a gastro-jejunostomy performed Five of these patients are absolutely well (55 5 per cent), and four complain. These four patients all appear to have considerable pain, have to be very careful what they eat, and one of them vomits. One of these operations was done on a man whose ulcer had perforated a year previously The other three men had ulcers with very little fibrosis around them. It would not be right to accept this percentage of cure from gastro-jejunostomy as a true picture of results, as the numbers are so small. Nevertheless, the difference between it and that following duodenectomy is very great, and justifies us in regarding gastro-jejunostomy as an inferior method of cure

Conclusions

1. When the results of the operative treatment of medically intractable gastric and duodenal ulcers by a single operator using different methods are compared it is found that a large proportion of patients are cured and the remainder improved

2. Partial gastrectomy will cure 80 per cent of such gastric ulcers It can be carried out in 77 per cent of all cases and has a mortality of 4 25 per cent

3 Gastro-jejunostomy is accepted as a much inferior method but sometimes gives remarkable relief in the most unfavourable conditions

4. Partial duodenectomy will cure 85 per cent. of duodenal ulcers which have not responded to medical measures It can be done in 71 per cent. of cases and has a mortality of 4 per cent

5 Gastro-jejunostomy is a much inferior operation to partial duodenectomy. In the small group of patients in whom it was used only 55 per cent were cured. This result agrees generally with those previously published by myself,[4] by R Lewisohn,[5] D Forsyth[6] A. Widler,[7] von Haberer and others, but contrasts strongly with those results published by Sir Berkeley Moynihan[8] J Sherren,[9] A. J. Walton,[10] and D. Balfour[11]

It is suggested that either a different class of case is dealt with by the two groups or a less exacting standard of cure is demanded by the one and that the only method of arriving at the truth of this matter is for each individual surgeon to compare the relative values of partial duodenectomy and gastro-jejunostomy in his own practice

A STUDY OF THE PATELLAR REFLEX IN EPIDEMIC ENCEPHALITIS,

WITH SPECIAL REFERENCE TO THE EFFECT OF HYOSCINE UPON IT

BY J S HARRIS, M D EDIN, D P M,
SENIOR ASSISTANT MEDICAL OFFICER, MAUDSLEY HOSPITAL, LONDON

DESPITE the great importance of the patellar reflex, very few attempts have been made to examine in detail the variations to which it is subject in health and disease In the present paper an account is given of an attempt to study closely the knee-jerk in cases of epidemic encephalitis The effect of hyoscine and stramonium on this reflex is also dealt with

Description of Apparatus

The apparatus employed consists essentially of two parts, one concerned with the application of the stimulus to the patellar tendon, the other with the graphic representation of the knee-jerk thus obtained.

The first part is composed of a hollow metal cylinder with a bore of about ¾ in., through which runs a metal piston At one end of the latter is a handle and at the other end a small rubber disc, ¾ in in thickness By means of the handle the metal piston can be pulled back for a certain fixed distance against the resistance of a spring which is contained within the metal cylinder Once the piston has been forced back in this way it can be fixed by means of a small catch If this catch is slipped the spring will recoil carrying with it the metal piston and causing the rubber disc to strike against the patellar tendon A stand is employed in order to fix the cylinder with the contained piston at the required level

The recording portion of the apparatus consists of a lever with its fulcrum placed close to one end The short arm of the lever carries a pointer which writes on a revolving drum driven by clock-work The long arm of the lever is attached to the posterior aspect of the patient's ankle Thus it will be seen that any movement of the patient's foot will be accompanied by a corresponding excursion in the opposite direction of the pointer writing on the drum The latter is arranged in such a way that it slides to and fro on two parallel strips of metal thus keeping its long axis always in the same direction The apparatus described above was assembled according to Dr F. Golla's directions

Method of Obtaining a Graphic Representation of the Knee-jerk

The patient's right leg is stripped to a point a few inches above the knee He is placed in a chair which is raised on blocks and which has attached to it a simple contrivance for fixing the right leg above the knee The right leg is allowed to hang over the edge of the chair and of course cannot touch the ground as the chair is raised on blocks The patient's left foot is slipped behind the left leg of the chair so that it will not interfere with the movement of the long arm of the lever The latter is attached to the patient's ankle in the region of the tendo Achillis The direction of the long arm of the lever is compared with that of a special metal guide which is fixed below the fulcrum in such a way that it is at a constant angle to the long axis of the drum

By altering the position of the stand on which the drum, fulcrum, and direction guide are fixed, the long arm of the lever can be made to run parallel with the direction guide with the result that the pointer is always inclined in the same direction when it is recording the knee jerk on the drum The latter, on which has been placed a blackened paper, is moved forward until the pointer is resting lightly upon it. The pointer is raised and the drum is made to rotate until it has reached its maximum speed when the pointer is allowed to rest on the revolving blackened paper. A signal is given to the person operating the stimulus-producing apparatus and he frees the piston, which strikes the patellar tendon and causes the reflex. As the leg swings forwards and backwards a corresponding movement of the pointer in the opposite direction occurs and a graphic representation of the patellar reflex is thus obtained

It will be obvious that one can compare the general contour of the curves and the time taken in different cases, but it is not possible to compare the amount of the excursion since its graphic representation will be influenced by the length of the patient's leg from knee to ankle In order to find the length of time taken, each record is marked by a time signal which shows hundredths of a second.

Description of Normal Knee-jerk.

Below will be seen a graphic representation of the normal knee-jerk. (Fig 1.) The tracing shows three distinct curves, two below and one above the axis line. The axis line corresponds with the resting position of the leg just before the knee-jerk is elicited The first curve is below the axis line and corresponds with the forward swing of the leg immediately the patellar tendon has been struck. The second curve, which is above the axis line, is caused by the backward swing of the leg which occurs as soon as the extensor muscles of the knee relax The third curve is below the line and represents a secondary forward swing of the leg If the drum on which this record was taken had been larger, more secondary swings forwards and backwards would have probably been recorded, and these would have become less and less marked until finally the leg would have come to rest and the pointer would have again coincided with the axis line, as was the case before the patellar tendon was stimulated Every normal knee-jerk shows at least one secondary swing, and the majority show more than one

The time taken by each of these first three curves varies within the following limits —

1st curve or primary forward swing	45 to 60	hundredths of a second.
2nd curve or primary backward swing	26 to 44	
3rd curve or first secondary forward swing	26 to 50	

The total time taken by the first three curves varies from 110 to 145 hundredths of a second.

Interpretation of the Knee-jerk Tracing in the Normal Person

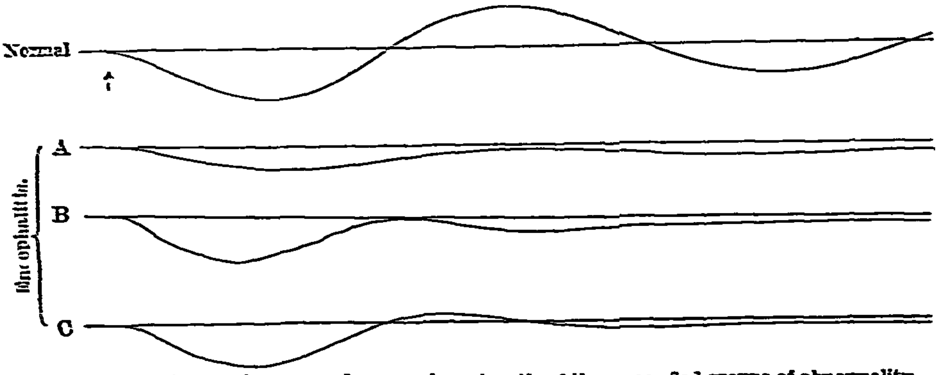
Some difficulty is experienced in the interpretation of the meaning of the normal knee-jerk tracing The primary forward swing of the leg, portrayed on the drum as a curve situated below the axis line, is of course due to the contraction of the extensor muscles of the knee, but the interpretation of the other curves, above and below the axis line, is less obvious The primary backward swing of the leg, shown on the tracing as a curve above the axis line, occurs immediately the extensors of the knee relax and appears to be capable of two interpretations

In the first place, the sudden contraction of the extensors of the knee following upon the application of the stimulus to the patellar tendon is accompanied by a lengthening of the opposing flexors This sudden stretching may be a secondary reflex contraction of the latter with the consequent backward swing of the leg Or, in the second place, the primary backward swing of the leg might be regarded as due to a pendulum-like movement, the leg below the knee behaving like an inert body and, after the contraction of the quadriceps has ceased, swinging backwards and forwards a number of times before finally coming to rest If both these explanations might apply to the primary backward swing they might also apply to all the secondary swings of the leg

As regards the first theory it has been demonstrated by Golla [1] by means of an electromyographic method that a contraction of the flexors of the knee does actually take place in the patellar reflex The antagonists enter into contraction about 10 sigma after the beginning of the response of the quadriceps By means of a mechanical method this contraction of the flexors was shown by Gordon Holmes,[2] though with his method the time relations could not be determined The electromyographic records published in a subsequent paper by Golla and Hettwer [3] show, however, that the flexor contraction does not outlast the reflex quadriceps contraction There seems to be no reason for attributing the backward swing of the leg to this flexor contraction, as Golla has pointed out that, when the patellar reflex is elicited as an isometric contraction there is no active rebound, although the flexor contraction coexists with the quadriceps contraction

The second theory, which holds that the leg below the knee, once the contraction of the quadriceps has ceased, behaves like an inert body and swings backwards and forwards after the manner of a pendulum, appears to be the correct one for the following reason. If, instead of causing the forward swing of the leg by striking the patellar tendon, the leg is passively moved forwards to the same extent as would occur when the patellar tendon is struck and is then suddenly released the leg will swing backwards and forwards for a short period of time in a pendulum-like manner. Obviously in this case there has been no sudden lengthening of the flexors of the knee and hence a reflex contraction due to sudden stretching of these muscles could not occur, and yet a primary backward swing and some secondary swings are obtained very similar to those which follow elicitation of the patellar reflex. This pendular movement of the leg below the knee is dependent on the presence of only a small amount of postural tone, as is the case in the normal person.

FIG. 1.



Normal knee-jerk curve and curves characteristic of three specified groups of abnormality.

Interpretation of the Knee-jerk Tracing in the Encephalitic

When dealing with the normal knee-jerk tracing it was suggested that the primary backward swing of the leg and all the secondary swings were due to the fact that the part of the leg below the knee after its primary swing forward as the result of stimulation of the patellar tendon, behaved like an inert body, and swung backwards and forwards after the manner of a pendulum before finally coming to rest. In cases of encephalitic Parkinsonism this movement is lost to a greater or less extent, due to the fact that in them there is a marked increase in the amount of postural tone present, as described by Foix[4] and Delmas-Marsalet.[5] In the normal person, if a limb be passively flexed, immediately the support is withdrawn the limb will return to its former resting position. In the case of encephalitic Parkinsonism the return to the former position is retarded on account of the increased postural tone in the muscles involved. Hence in the case of the knee-jerk in the encephalitic Parkinsonism the leg, once it has swung forwards, tends to remain in a fixed forward position or returns to the resting position (the axis line) at a much slower rate than the normal.

Description of the Knee-jerk in Encephalitis.

In all 18 patients suffering from mental symptoms associated with chronic epidemic encephalitis were examined, and 13 of them gave knee-jerk curves which differed from the normal. It was found that these abnormal curves could be divided into three distinct groups:—

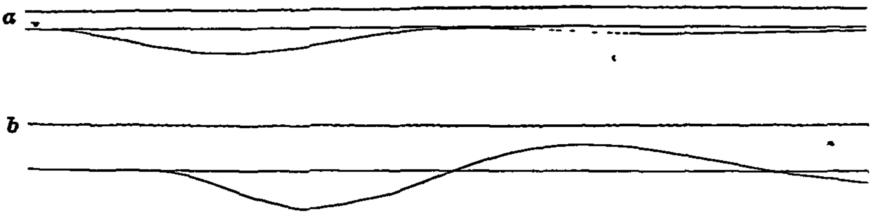
Group 1—The leg swung forwards executing the primary forward swing, but instead of immediately swinging backwards, remained in a fixed forward position, thus tracing on the drum a curve which lay wholly below the axis line (Fig. 1. (A)) Six cases fell within this group (see table, Nos. 1 to 5)

Group 2—The leg, after its primary forward swing, fell back until it reached its resting position, and then swung forwards again, thus tracing on the drum a curve which lay below the axis line, but touched it at one point. (Fig. 1 (B)) Two cases fell within this group (see table, Nos 6 and 7)

Group 3—The leg completed the primary forward and backward swings in the normal manner, then swung forwards again and remained in a fixed position. (Fig. 1 (C)) The five cases in this group gave tracings in which the first two curves appeared normal, but the pointer, once it had completed the second curve, remained below the axis line (see table, Nos. 8 to 12)

All the cases composing these three groups showed clinically muscular rigidity to a more or less marked extent The remaining five cases out of the total of 18 gave knee-jerk tracings which appeared normal. Only one of these five cases from the clinical standpoint showed definite muscular rigidity.

FIG. 2



Knee-jerk curves showing effect of hyoscine on encephalitis—(*a*) before, (*b*) after administration.

Effect of Hyoscine

(1) *On the normal knee-jerk*—The normal knee-jerk was little if at all influenced by the injection of hyoscine. The time taken by the curves was in some cases increased, in others diminished, but the general contour of the tracing conformed to the normal.

(2) *On the encephalitic knee-jerk*.—In 12 of the 13 cases of encephalitis which gave abnormal knee-jerk tracings the hypodermic injection of hyoscine hydrobromide caused, in from two to three hours, the general contour of the knee-jerk tracing to approach more closely to that of the normal. In some of the cases this beneficial effect on the tracing was more marked (Fig 2), (*a*) before hyoscine, (*b*) after hyoscine The table contains the details of these 12 cases before and after hyoscine

Any increase in this reading after hyoscine would mean that the knee-jerk had become more active or even definitely exaggerated Similarly, any decrease would signify a less active or even sluggish knee-jerk A glance at the table will show that the action of hyoscine in this respect varies greatly in different cases. It is interesting to note that those cases which presented abnormal knee-jerk tracings and in whom hyoscine caused an improvement in the general contour of the curves also benefited clinically from the exhibition of this drug The one case which showed an abnormal tracing which was not made to approach more closely to the normal from the clinical standpoint benefited only slightly when treated with the drug Of the five cases which gave normal types of knee-jerks three benefited clinically from the drug and two were uninfluenced

Pr F S = Primary forward swing
Pr B S = Primary backward swing
Sy F S = Secondary forward swing
R = Remained below axis line

Wherever the pointer failed to return to the axis line (position of rest of leg) and remained in a fixed position below the line the letter " R " is inserted Where, however, the pointer swung freely completing one or more curves the time taken by each curve is noted in hundredths of a second The amount of excursion of the leg during the primary forward swing is shown in the tracing by the distance the first curve reaches below the axis line This distance is shown in a separate column in centimetres

A few cases of katatonic dementia præcox were examined with a view to ascertaining whether, on account of the muscular rigidity present, the type of knee-jerk tracing would resemble that of the encephalitic, and if so, whether hyoscine would exercise any similar beneficial effect on the general contour of the curves It was found that cases of katatonic dementia præcox presented knee-jerk tracings which closely resembled those found in group I of the encephalitics, but that hyoscine failed to make the curves approach the normal, in striking contrast to the effect of this drug in cases of encephalitis

Certain French writers [6] have reported that the exhibition of stramonium by the mouth is attended with good results in cases of Parkinsonism They claim that among other things the rigidity is to a large extent removed although the tremor is unaffected In view of this report five of the cases of encephalitis under review were placed on tinct stramonii (♏ xxv t i d) and their knee-jerks investigated It was found that in one case the knee-jerk tracing was made to approximate more closely to the normal, the other four were unaffected Clinically three of the cases showed a very slight improvement, but the benefit obtained fell far short of that caused by hyoscine

Conclusions

1 The great majority of cases of epidemic encephalitis especially those which exhibit Parkinsonism give a definitely abnormal patellar reflex 2 Hyoscine, which has been shown to produce marked temporary improvement in these cases causes the abnormal knee-jerk to approximate to the normal 3 Cases of katatonic dementia præcox with well-marked rigidity show abnormal knee-jerks which closely resemble some of those found in encephalitic Parkinsonism, but hyoscine signally fails to exert a beneficial action on these abnormal knee-jerks

In conclusion I would like to thank Dr F L Golla, the Director of the Pathological Laboratory of the Maudsley Hospital, at whose suggestion these investigations were undertaken, for his unfailing interest and assistance To Dr N Roberts, the medical superintendent of West Park Mental Hospital, I am indebted for permission to publish the particulars of the cases investigated

Clinical and Laboratory Notes.

A NOTE ON
CASTOR OIL IN ACUTE APPENDICITIS [1]

BY G M TANNER, M A CAMB , M R C S ENG ,
HOUSE SURGEON, ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

IT is generally agreed that to give castor oil in a case of acute appendicitis is bad practice , it is contrary to the established principle that an inflamed structure should be rested Nevertheless, patients with acute appendicitis are liable to be given castor oil either by their relations, before the doctor is called in, or by the doctor himself, who may give a dose of it as treatment for abdominal pain whose cause is as yet undiagnosed

The belief that castor oil does, in fact, cause acute appendicitis to take a more violent course than it otherwise would is supported by an analysis of a series of 50 consecutive cases of this disease admitted to beds in Addenbrooke's Hospital since I became house surgeon Cases of chronic and quiescent appendicitis which have been operated upon were excluded from the series , all the cases were sent in as acute " emergencies " and were operated upon forthwith as such

In six of these 50 cases the appendix was only mildly inflamed—that is to say, the inflammatory changes were limited to the mucous membrane In 21 the appendix was acutely inflamed, the whole organ being swollen and thickened, and lymph being present in some cases on the peritoneal surface The remaining 23 cases were all more advanced In ten of them the appendix was gangrenous but not perforated, and no pus was present , the other 13 were all appendix abscesses, and in six of these the appendix was found to have perforated

In every case, as matter of routine, the patient or the relations were definitely questioned about purgatives, and in eight of the 50 cases it was stated that castor oil had been administered In all of these eight cases the appendix was gangrenous, and in two it was perforated In six of them pus was also present, and one of the patients died It is significant that whilst only one-sixth of the 50 patients had had castor oil, this one-sixth included half those who developed an appendix abscess

Of the 50 cases the following three were fatal —

CASE 1 —A man, aged 37, came in on the fourth day of his illness with an appendix abscess Jaundice was first noticed on the day after his operation, and he died on the eighth day of portal pyæmia

CASE 2 —A man, aged 55, had dosed himself with pills at the onset of illness, and came up on the third day with a large appendix abscess He did very well for a few days after operation, but then he developed acute obstruction due to adhesions, and he died on the ninth day after a second operation

CASE 3 —A woman, aged 61, had been given castor oil by a friend at the onset of abdominal pain and came up on the fourth day Her appendix had completely disintegrated and she had extensive peritonitis and fæcal matter free in the abdomen The abdominal cavity was opened and drained, but she died of heart failure on the fourteenth day after operation

[1] Read at a meeting of the Cambridge University Medical Society on March 4th

I think that two reasons may be given for the harmful effect of castor oil upon the course of acute appendicitis One is the obvious one—namely, that the oil further irritates the already inflamed and irritated gut and thus accelerates the pathological changes that are taking place The second reason is that it delays operation because it means that whoever gives the oil is going to temporise with the case the appendix being left to give rise to an abscess and possibly to perforate It may be noted that all three fatal cases were late cases; in one acute symptoms had been present for three days, and the other two for four days

The 50 cases—or rather the 47 survivors—may be analysed in a different way In 13 cases the patients were admitted to hospital on the first day of their illness and were discharged from hospital in an average time of 11 days from admission. In eight cases the patients came in on the second day, and their stay in hospital averaged 13 days The remainder, admitted on the third day and later, spent an average of 16 days in hospital

In conclusion, I may mention a case which is not included in the 50, because it is more recent.

A girl, aged 14, was seized with abdominal pain one day at noon One hour later her mother gave her a dose of castor oil, which made the pain much worse. A doctor was called in later in the day, diagnosed acute appendicitis, and sent her straight into hospital. She was operated upon eight hours after the commencement of her pain. Her appendix was long, red, and tensely distended and covered on the outside with lymph Its lumen was found to be full of that yellowish, intensely irritating fluid motion which is associated with castor oil, and the mucous membrane was full of small hæmorrhages.

I think it is clear that the pathological changes in this case were being accelerated by the castor oil

A CASE OF

UTERUS DIDELPHYS WITH PREGNANCY

ALTERNATING IN THE TWO HORNS.

By J Lloyd Davies, M D M R C P Lond
F R C S Edin,
Hon Gynæcologist to the Swansea General Hospital,
and
C. J. Cellan-Jones M.B, B S Durh
F R C S Edin

Pregnancy has often been recorded in a congenitally defective uterus, even where there is independent development and complete failure in fusion of the Mullerian ducts Usually, however, atresia in some part of the cervix or vagina of one or other side only allows of the development of a fertilised ovum in a single horn; so that when evidence is found at operation of pregnancy occurring at intervals in both horns of a double uterus, the case is worthy of description.

A woman aged 27 was brought to the Swansea General Hospital by Dr D B Harrington on Dec. 27th, 1926 She had reached term in her second pregnancy, having been delivered four years previously, by Cæsarean section of a stillborn male child weighing 10½ lb Operation had been withheld in this instance until labour had been obstructed for a period of four days

On abdominal examination the fundus was found to be at the level of the xiphoid process and directed towards the right side. Fœtal heart sounds were plainly audible. A distinct mass was palpable above the pubes to the left of the middle line. The vulva was normal in appearance, but vaginal examination disclosed the presence of two distinct passages each containing a normal cervix and external os, separated from one another by a lax median septum. Both cervices were softened and the external os upon the right side admitted one finger

Labour was allowed to continue and eventually the membranes ruptured but the head did not descend. On Dec 28th, as the patient was extremely anxious for a living child, an abdominal Cæsarean section was decided upon. Laparotomy revealed a condition of complete uterus didelphys with a well-marked fold of peritoneum, or vesicorectal ligament as it is termed, occupying the deep fissure between the horns. The left horn, which was of a size corresponding to a three months pregnancy, exhibited, on its anterior surface, the scar of a previous Cæsarean section. From the right horn a living female child, weighing 6¼ lb was delivered. Permission to sterilise the patient could not be obtained although the danger of future pregnancies was explained.

Recovery was uneventful and when they were last seen, on April 7th, the mother and her child were both very well

An additional point of interest in this case is that the uterine abnormality produced an obstructed labour in both pregnancies whereas, according to most authorities, a double uterus does not usually interfere with spontaneous delivery

Medical Societies.

ROYAL SOCIETY OF MEDICINE

SECTION OF MEDICINE.

At a meeting of this Section held on April 26th, the chair being occupied by Dr **Hugh Thursfield**, the President, Dr. **A Osman** and Dr. **H Carter** read contributions on the

Prevention of Scarlatinal Nephritis

Dr Osman said in an investigation into the treatment of nephritis by means of doses of alkalies it seemed possible that benefit might be derived from using alkalies prophylactically With that object in view, and through the kindness of Dr. T. H. Woodfield, the superintendent of the Park Fever Hospital, Hither Green, a certain number of wards were set aside for a number of months, and alkalies were given to the occupants of those beds as a routine, in small doses, in order to test the matter In some of other wards alkalies were not given to the patients, and these were used as controls In an experiment of this kind, on a somewhat large scale, it was difficult to follow out the minutiæ in all the investigations as one would like especially in regard to dosage. It was only possible to give a standard dose over an arranged period and watch the results After a time it was found that a small dose 0 90 g a day was not sufficient and so it had to be increased until a dose was reached at which albuminuria and nephritis appeared to be at any rate less common that in the cases in the control wards The figures which Dr. Carter would give were not to be considered final, but they were those obtained to date, they covered the 14 months during which the experiment had been in progress

Dr Carter projected on to the screen tables of figures relating to the cases observed The first table showed the cases which had been treated in the way described in the five wards set apart during the first three or four weeks of the scarlet fever. The disease in these patients was of varying severity and the range of age-incidence the usual one—4 to 10 years Of the 620 patients in this group, four developed nephritis: there were no cases of albuminuria Three of the four patients developed the nephritis between the twenty-second and the twenty-fifth days of the disease, at a time when the alkalies were given only over a period of three weeks so that when the nephritis developed the prophylactic treatment had already been discontinued In all four the urine was strongly acid One of the four cases was fatal This child had developed nephritis on the fourteenth day of the disease; death took place nine days later, and for seven days before the end suppression of urine had been complete Sections of the kidney of that case were examined by Dr. J E McCartney and also by Prof A. Stokes of Guy's Hospital, and both reports agreed that a previous nephritis lesion existed. Dr. McCartney's report was that it was subacute interstitial nephritis with antecedent glomerular change. The table showed a total incidence in these special wards of

0 6 per cent nephritis, albuminuria nil The second table embraced the remainder of the cases of scarlet fever in the hospital—i e , those which had not been treated with alkalies—and the 316 cases showed an incidence-rate of nephritis of 2 9 per cent The third table showed a comparison with the figures obtained from a fever hospital for acute cases, an institution which drew its cases from the same localities as that already named The period covered was the same Here, out of 336 cases, there were 7 of nephritis, 12 of albuminuria The total incidence was 5 5 per cent , and it corresponded, roughly, with the incidence in the London area in what could be regarded as a mild type of the disease After obtaining such encouraging results it seemed possible, Dr Carter said, by employing some modification of Sellard's test for alkaline tolerance and giving a set dose of alkalies, to arrive at an opinion as to which cases of scarlatina were likely to develop nephritis during that illness, and to aid treatment by estimating the calcium bicarbonate curve during the course of the scarlet fever

Discussion.

The PRESIDENT invited Dr. Osman to say why he was led to carry out this alkali treatment and why he considered this method was likely to diminish the incidence of nephritis

Dr OSMAN replied that he had noticed, in the treatment of nephritis of all types, that when the urine of patients was alkaline, the amount of albumin passed was less, and the volume of urine voided was more, than when the urine was acid That led him to a study of the alkalinity of the blood and related questions Whilst working on that, he encountered a case of anuria, caused apparently by a large dose of sanocrysin By giving that patient large doses of alkalies the anuria was overcome, in Dr Osman's opinion, because of the alkalies It seemed to him possible, therefore, that, in other cases, if metallic drugs were going to be used, the toxic effect of such drugs might be warded off by giving alkalies prophylactically , and in one or two instances that seemed to be the case Then it occurred to him that the experiment might be tried on a larger scale, and that the only condition under which one was likely to meet with a supply of cases of nephritis was in connexion with scarlet fever

Dr. J D ROLLESTON emphasised the very low incidence of nephritis in scarlet fever at the present day, and said that for this reason it was difficult to know how far to attribute to treatment what might possibly be simply the natural course of the disease The medical officers of all fever hospitals seemed to agree as to the great dearth of cases of nephritis in scarlet fever , in the fever hospital with which he was connected he was unable to show a single case of nephritis in the first six months of last year to the students That experience was largely paralleled in Paris and other places on the continent The form in which Dr Osman and Dr. Carter gave the alkalies was not mentioned An important question was as to whether prophylactic measures would do harm The only other which had been tried in this disease, as far as he knew, was the administration of urotropin, and that did harm, in that it caused cystitis Urotropin for this purpose had now been given up because of the cystitis it produced He did not think the alkaline treatment would do harm, though the patient probably did not find it pleasant to be given large quantities of alkali

Dr PARKES WEBER said it had always seemed to him that, in one respect, what occurred in fevers imitated what took place when people in health suddenly began to take excessive muscular exercise—there was concentrated urine which showed copious deposit of urates after standing In addition, there was often disagreeable muscular stiffness He thought the giving of a certain amount of bicarbonate of soda prevented or relieved the symptoms due, in healthy people, to excessive muscular exercise, and that therefore alkalies would be useful in fevers Probably urotropin was not likely to be of much use in this connexion If given with alkali instead of with acid, so as to prevent the onset of cystitis, it would be possible to ascertain whether urotropin would be of benefit in this disease prophylactically

Dr J A RYLE said that Dr Osman had modestly refrained from giving any indication of the fact that for several years he had been carrying out a patient and most laborious research on alkaline therapy in nephritis But he had kept his results to himself until he was sure of his ground. The cases treated by him at Guy's Hospital had been most carefully controlled, and he (Dr Osman) had concluded that there was much to be said in support of the method, improvement being possible especially in water-logging nephritis , here the treatment caused disappearance of the œdema and the albumin in a way which was not seen in the absence of this treatment Given a case of scarlet fever, it seemed clear that if the urine was over-acid there was more likelihood of the patient having nephritis than if it was not over acid. The figures so far produced showed how, conceivably, nephritis might be prevented in a certain proportion of cases of scarlet fever by administering alkalies If there was any support for the contention it was very important to pursue the matter further, and he hoped that those in charge of fever hospitals would take note of what Dr Osman was doing, and would afford him help and encouragement in an investigation of real importance

Dr KINGSTON BARTON referred to three kinds of nephritis after or with scarlet fever, and said it was not clear what was the cause of the nephritis in scarlet fever, whether it was the causal microbe or its toxin If the microbe was a streptococcus probably two kinds passed through the kidney. The preliminary symptoms took the form of an acidosis, and that was probably why alkalies did good He asked exactly what alkalies Dr Osman gave It was desirable that pathologists should say what were the causes of the three types of nephritis he had mentioned

Dr OSMAN, in reply, said he agreed that there had been a considerable decrease of nephritis in scarlet fever during recent years The form in which he gave the alkalies in these cases was a mixture containing equal parts of potassium citrate and sodium bicarbonate The reason for selecting this mixture was partly because potassium salts were known to be effective in causing diuresis ; but if large doses had to be given potassium salts could not be given alone, especially not to children, on account of their liability to cause diarrhœa The mixture seemed to obviate that difficulty

---

SECTION OF UROLOGY

AT a meeting of this Section held on April 28th, Mr GIRLING BALL, the President, in the chair, Sir THOMAS HORDER spoke on the

MEDICAL ASPECTS OF HÆMATURIA

He gave a list of cases of gross, frank hæmaturia which had been observed in his medical wards at St Bartholomew's Hospital during the last five years In 54 of these hæmaturia had been either the main or a very important and striking symptom The *final diagnoses when these patients* left the hospital were more or less as follows Out of the 54 cases, 20 were diagnosed as acute nephritis, 7 as chronic nephritis, 4 as renal calculus, 4 as infective endocarditis, 3 had infection of the urinary tract which was thought to be the cause of the hæmaturia, 2 were suffering from mitral stenosis (and presumably, therefore, had renal infarction), 2 were cases of purpura, 2 were thought to be of prostatic origin Of the remainder, 4 were diagnosed Addisonian anæmia, polycythæmia (Vaquez's disease), encephalitis treated with hexamine, and hæmaturia probably due to intensive salicylate treatment, whilst 5 cases remained unclassified Of these last 5 cases he thought that 2 came into that very ill-defined group of hæmaturias which had been called essential hæmaturia.

Acute Nephritis

Acute nephritis, continued Sir Thomas Horder, was obviously by far the commonest disease coming nowadays to the physician for hæmaturia. He found it difficult to say which type of infection had the greatest tendency to produce bleeding. In cases in which there was no recognised source of infection or site of focal sepsis, attempts to decide on the pathogenesis were very disappointing. Again and again these cases—the majority of them in children—were admitted to hospital, and a survey of their past history and present condition left a complete blank as to the nature of the infection. Many theories had been advanced, but none of them were borne out by bacteriological or other evidence. With regard to chronic nephritis, he had nothing to add to the accepted views. In patients subject to latent parenchymatous nephritis it seemed to take very little in the way of subinfection to produce hæmaturia. The term "renal epistaxis" had been rather diverted from Gull's original meaning to a group of cases now called "essential hæmaturia." There was no reason why the term "renal epistaxis" should not be applied to a form of bleeding from the kidney which was not associated with vascular changes, but that was not its original meaning. Some authorities stated that bleeding was more prone to occur where a chronic nephritis was syphilitic in origin. To judge by the positive Wassermann in cases of chronic nephritis—if that could be taken as a guide—there was, in the four cases of which he had notes, no special tendency to bleeding; but it was sometimes said that syphilitics tended to a hæmorrhagic type of nephritis.

Renal Calculus.—Infection.—Heart Disease.

His next group consisted of cases in which there was renal calculus. He sometimes wondered if renal calculus could be diagnosed in the absence of hæmaturia, assuming that the radiogram was negative. There was a danger of overlooking a calculus when infection was also present and easily demonstrable. Another group of cases comprised those in which there was acute infection of the urinary tract. One very deceptive case in this group showed a papillomatous condition of the bladder; the patient had had chronic cholecystitis for some time, but the urinary tract infection was quite marked. It was, perhaps, necessary to be on the look-out for a double cause of hæmorrhage—i.e., papilloma in the pelvis of the kidney plus some infection of the urinary tract. Two of the cases in his list were labelled prostatic. The patients were men over 60 years of age, and the diagnosis was made in conjunction with a surgical colleague. One of the patients had hyperpiesis, which might have increased the tendency to bleeding.

Turning to hæmaturia in association with heart disease, Sir Thomas Horder said that there were three heart conditions illustrated in his group—namely, septic endocarditis, mitral stenosis, and dilated heart. One of the cases of infective endocarditis was that of a girl of 18, who complained greatly of pain, so much so that he thought there must be some feature other than septic infarction, but she died in hospital from cerebral embolism, and there was nothing found post mortem to account for the pain except renal infarction. Coming to certain blood states, he mentioned two cases of purpura, both of them of Henoch's type. The relation of purpura was a very complex one. The kidney might bleed as an expression of the purpuric state. The toxic element causing purpura might cause the kidney to bleed, but hæmorrhages into the kidney themselves caused renal changes very closely allied to, if not identical with, nephritis, so that it was sometimes very difficult to say what was the sequence of events. The case of polycythæmia (Vaquez's disease) was very interesting. A woman had been under observation several times in St. Bartholomew's Hospital and elsewhere for retinal hæmorrhage and other conditions. A few hours after sea-bathing she had an attack of hæmaturia, which persisted for the six weeks until her death, and the loss of blood was so considerable as to reduce what had been a polycythæmia down to figures which were just about those of the normal count.

Of the unclassified cases (five), he felt sure that one, or perhaps two, would be put down as essential hæmaturia by those who considered that there should be a group of cases of hæmaturia to which that professional label was given. One of these unclassified cases was that of a patient with aneurysm of the thoracic aorta; she had a profuse hæmaturia four days before death. Another case might possibly be regarded as a calculus or nephrolithiasis. The most typical case of essential hæmaturia was in a man of 33 (from literature he noted that most of these cases occurred between the ages of 20 and 40), who, in 1921, passed blood in the urine. He was examined with the cystoscope and nothing wrong was found. Up to March, 1923, he came back to the hospital three or four times with short attacks of hæmaturia. Nothing in his condition or his past history suggested a reason why he should have this tendency to bleed. Radiology was quite negative, and he had no dysuria. There were no signs of arterial changes, no hyperpiesis, no albumin or mucus in the urine. He did not know what had happened to him since, but he regarded this as a type of case which might go under the name of essential hæmaturia. Amongst his list of cases there did not happen to be an instance of tuberculosis, or of hæmaturia as the result of drugs, except hexamine. This was a case of acute encephalitis. The patient was given not a heroic dose of hexamine—20 gr. six-hourly—and at the end of the third day there was a profuse hæmaturia.

The PRESIDENT said that Sir Thomas Horder's remarks had illustrated the desirability of collaboration between physicians and surgeons in such a field as this. Many cases which used to be called essential hæmaturia were now, as a result of more perfect methods of investigation, classified in other categories.

Dr. GEORGE GRAHAM thought it remarkable that in cases covering five years in the medical wards there should not have been an instance of oxaluria. He mentioned a case of hæmaturia in an elderly lady which had come under his observation and in which there appeared to be nothing to account for the condition except the fact that she had been eating a great deal of ginger. The oil of ginger, though nothing like so potent as turpentine, was said to cause hæmaturia.

Sir JOHN THOMSON-WALKER said that it did not seem to him to have been brought out quite clearly whether hæmaturia was the primary or most important symptom, or was only a secondary symptom. At the same time, having had doubts on the subject, he had been convinced by Sir Thomas Horder that there were medical cases of hæmaturia or medical aspects of the condition. Sir Thomas Horder had rather seemed to imply, in speaking of the prostate, that one was likely to get more hæmorrhage in a malignant prostate, but in fact hæmorrhage occurred much more easily and freely from a large œdematous prostate than it did from a malignant prostate.

Mr. HUGH LETT said that in his experience the very worst hæmorrhages in connexion with the enlargement of the prostate were in cases in which stone was present in the bladder as well.

Mr. SWIFT JOLY asked whether in chronic interstitial nephritis it was the common experience to find the bleeding unilateral. He had cystoscoped three of these cases, and in all of them the bleeding came entirely from one kidney.

Mr. NITCH SMITH said that he knew of one man who by accident was given a concentrated solution of hexamine, receiving 480 gr. of the drug, and it did not have the slightest effect in causing hæmaturia.

Sir THOMAS HORDER, in a brief reply, said that the physician saw all cases of hæmaturia as medical cases until he proved them to be surgical, and if the surgeon attended to all cases of hæmaturia as surgical until he proved them to be medical, and both physician and surgeon pursued their respective methods of approach to the bitter end, the patient got the benefit either way.

0 6 per cent nephritis, albuminuria nil The second table embraced the remainder of the cases of scarlet fever in the hospital—i e, those which had not been treated with alkalies—and the 316 cases showed an incidence-rate of nephritis of 2 9 per cent The third table showed a comparison with the figures obtained from a fever hospital for acute cases, an institution which drew its cases from the same localities as that already named The period covered was the same Here, out of 336 cases, there were 7 of nephritis, 12 of albuminuria The total incidence was 5 5 per cent, and it corresponded, roughly, with the incidence in the London area in what could be regarded as a mild type of the disease After obtaining such encouraging results it seemed possible, Dr Carter said, by employing some modification of Sellard's test for alkaline tolerance and giving a set dose of alkalies, to arrive at an opinion as to which cases of scarlatina were likely to develop nephritis during that illness, and to aid treatment by estimating the calcium bicarbonate curve during the course of the scarlet fever

Discussion

The PRESIDENT invited Dr Osman to say why he was led to carry out this alkali treatment and why he considered this method was likely to diminish the incidence of nephritis

Dr OSMAN replied that he had noticed, in the treatment of nephritis of all types, that when the urine of patients was alkaline, the amount of albumin passed was less, and the volume of urine voided was more, than when the urine was acid That led him to a study of the alkalinity of the blood and related questions Whilst working on that, he encountered a case of anuria, caused apparently by a large dose of sanocrysin By giving that patient large doses of alkalies the anuria was overcome, in Dr. Osman's opinion, because of the alkalies It seemed to him possible, therefore, that, in other cases, if metallic drugs were going to be used, the toxic effect of such drugs might be warded off by giving alkalies prophylactically, and in one or two instances that seemed to be the case Then it occurred to him that the experiment might be tried on a larger scale, and that the only condition under which one was likely to meet with a supply of cases of nephritis was in connexion with scarlet fever.

Dr J D ROLLESTON emphasised the very low incidence of nephritis in scarlet fever at the present day, and said that for this reason it was difficult to know how far to attribute to treatment what might possibly be simply the natural course of the disease The medical officers of all fever hospitals seemed to agree as to the great dearth of cases of nephritis in scarlet fever, in the fever hospital with which he was connected he was unable to show a single case of nephritis in the first six months of last year to the students That experience was largely paralleled in Paris and other places on the continent The form in which Dr Osman and Dr Carter gave the alkalies was not mentioned An important question was as to whether prophylactic measures would do harm The only other which had been tried in this disease, as far as he knew, was the administration of urotropin, and that did harm, in that it caused cystitis Urotropin for this purpose had now been given up because of the cystitis it produced He did not think the alkaline treatment would do harm, though the patient probably did not find it pleasant to be given large quantities of alkali

Dr PARKES WEBER said it had always seemed to him that, in one respect, what occurred in fevers imitated what took place when people in health suddenly began to take excessive muscular exercise—there was concentrated urine which showed copious deposit of urates after standing In addition, there was often disagreeable muscular stiffness He thought the giving of a certain amount of bicarbonate of soda prevented or relieved the symptoms due, in healthy people, to excessive muscular exercise, and that therefore alkalies would be useful in fevers Probably urotropin was not likely to be of much use in this connexion If given with alkali instead of with acid, so as to prevent the onset of cystitis, it would be possible to ascertain whether urotropin would be of benefit in this disease prophylactically

Dr J A RYLE said that Dr Osman had modestly refrained from giving any indication of the fact that for several years he had been carrying out a patient and most laborious research on alkaline therapy in nephritis But he had kept his results to himself until he was sure of his ground The cases treated by him at Guy's Hospital had been most carefully controlled, and he (Dr Osman) had concluded that there was much to be said in support of the method, improvement being possible especially in water-logging nephritis; here the treatment caused disappearance of the œdema and the albumin in a way which was not seen in the absence of this treatment Given a case of scarlet fever, it seemed clear that if the urine was over-acid there was more likelihood of the patient having nephritis than if it was not over-acid. The figures so far produced showed how, conceivably, nephritis might be prevented in a certain proportion of cases of scarlet fever by administering alkalies If there was any support for the contention it was very important to pursue the matter further, and he hoped that those in charge of fever hospitals would take note of what Dr Osman was doing, and would afford him help and encouragement in an investigation of real importance

Dr KINGSTON BARTON referred to three kinds of nephritis after or with scarlet fever, and said it was not clear what was the cause of the nephritis in scarlet fever, whether it was the causal microbe or its toxin If the microbe was a streptococcus probably two kinds passed through the kidney The preliminary symptoms took the form of an acidosis, and that was probably why alkalies did good He asked exactly what alkalies Dr Osman gave It was desirable that pathologists should say what were the causes of the three types of nephritis he had mentioned

Dr OSMAN, in reply, said he agreed that there had been a considerable decrease of nephritis in scarlet fever during recent years The form in which he gave the alkalies in these cases was a mixture containing equal parts of potassium citrate and sodium bicarbonate The reason for selecting this mixture was partly because potassium salts were known to be effective in causing diuresis, but if large doses had to be given potassium salts could not be given alone, especially not to children, on account of their liability to cause diarrhœa The mixture seemed to obviate that difficulty

SECTION OF UROLOGY

AT a meeting of this Section held on April 28th, Mr GIRLING BALL, the President, in the chair, Sir THOMAS HORDER spoke on the

MEDICAL ASPECTS OF HÆMATURIA

He gave a list of cases of gross, frank hæmaturia which had been observed in his medical wards at St Bartholomew's Hospital during the last five years In 54 of these hæmaturia had been either the main or a very important and striking symptom The final diagnoses when these patients left the hospital were more or less as follows Out of the 54 cases, 20 were diagnosed as acute nephritis, 7 as chronic nephritis, 4 as renal calculus, 4 as infective endocarditis, 3 had infection of the urinary tract which was thought to be the cause of the hæmaturia, 2 were suffering from mitral stenosis (and presumably, therefore, had renal infarction), 2 were cases of purpura, 2 were thought to be of prostatic origin Of the remainder, 4 were diagnosed Addisonian anæmia, polycythæmia (Vaquez's disease), encephalitis treated with hexamine, and hæmaturia probably due to intensive salicylate treatment, whilst 5 cases remained unclassified Of these last 5 cases he thought that 2 came into that very ill-defined group of hæmaturias which had been called essential hæmaturia.

as the removal of a mole by electrolysis or cautery often left a small scar, such a scar was quickly healed by a quarter or one-third pastille dose of X rays, without suppuration or keloid

General Discussion

The PRESIDENT agreed that vaccines were only of use for acute staphylococcal conditions The theory that eczema was a coccal dermatitis set up by scratching was opposed by the practical experience that protection acted satisfactorily in one case and unsatisfactorily in the next The dermatologist must have many strings to his bow. The speaker had never seen a case of psoriasis benefited by oral administration of arsenic, but a very high pressure needle might do a great deal of good Izal was just as good if not better Cases of lichen planus, on the other hand, did benefit from arsenic and a dozen injections of soamin usually cleared up the trouble In his experience impetigo had become more difficult to cure than it used to be. and hospital cases did better than private ones Possibly a certain amount of dirt and the formation of a thick yellow crust helped in the cure; certainly the mild thin case without crusts took a very long time to clear up He agreed that X rays were dangerous for this condition In pemphigus the whole thing depended on the nursing. He agreed that carbolic acid was good for lichenification. but not better than X rays He thought official silver nitrate solution was better than the recent silver preparations

Dr J MACL. MACLEOD spoke of the value of X rays for superficial wounds and for cracks about the ears and sides of the mouth in impetigo; one-half to three-quarters pastille dose the day after scraping lupus patches was harmless and valuable A few cases of pruritus ani had a basis of ringworm

Dr W KNOWSLEY SIBLEY did not agree that the treatment of eczema should be entirely external Infantile eczema, in his experience always occurred in the overfed, flabby child and went on indefinitely unless the diet were corrected Certain individuals were born with a dry skin which was extremely vulnerable throughout life, very slight trauma would produce eczema For these thyroid was of great value. An important point in the treatment of impetigo was to get the part thoroughly cleansed before the ointment was put on In his experience, many lichen planus patients had had no worry. Ultra-violet light, like X rays, was very good for acne but was quite harmless He preferred to give them alternately

Dr R PROSSER WHITE said he was satisfied there was such a thing as diathesis in eczema. Industrial cases were due to irritation of the skin and were easily cured in a certain time, but there was an idiopathic group which reacted quite differently. His treatment was purely external For the treatment of burns he had found carron oil with a small quantity of hypochlorite very useful He thought izal was bad for the skin because of its detergent action

Dr W. GRIFFITH expressed gratitude to Dr Adamson for laying stress on real methods of treatment and not on fashionable fads and agreed with him that very few skin troubles could be cured by the internal administration of drugs. Much of the reputation of arsenic was unfounded but it was excellent in some of the bullous eruptions, such as dermatitis herpetiformis Nor did he know any skin disease that could be cured by dietetic measures Infantile eczema might occur in any kind of infant Myxœdema could be cured by thyroid, but he did not think ichthyosis could be He thought it important to be definite about the uselessness of vaccines, as so many practitioners sent cases up for vaccine treatment He doubted whether any spa treatment was superior to treatment obtainable in London

Dr G B DOWLING said that carbolic acid treatment of onychia had proved almost invariably successful in his hands He referred to recent work on napkin rashes, and their treatment by soaking the napkin in a 1/4000 solution of perchloride of mercury, which stopped the growth of the bacillus which converted urea into ammonia and so irritated the skin

Dr A C ROXBURGH said that this "napkin" treatment had worked well at St Bartholomew's Hospital.

Dr S. R KAPOOR said there were four types of skin which inclined to show eczematous states sooner or later—the florid, coarse, thick skin, the thin anæmic skin, the seborrhœic skin, and the ichthyotic skin He had had very good results with acid nitrate of mercury in tuberculous conditions, as suggested by Dr Adamson.

Reviews and Notices of Books.

THE MEDICAL ANNUAL

A Year Book of Treatment and Practitioner's Index. Forty-fifth Year Bristol: John Wright and Sons Ltd., London: Simpkin, Marshall, Hamilton, Kent and Co, Ltd 1927 Pp 624. 20s.

THE "*Medical Annual*" is a dictionary of practical medicine and many contributors, most of them for many years, have watched the progress of their specialties on behalf of the editors This stability of outlook makes for a continuous series, so that the habit of reading the "Medical Annual" is rarely lost when once it has been acquired Indeed, though an isolated volume gives much useful information as to recent advances, these can hardly be consolidated in so short a period as one year, and the process whereby discovery is made, doubted, confirmed. and established in routine practice has generally to be sought and followed through several issues of this excellent annual. Those responsible, under the editorial direction of Dr. Carey Coombs and Mr. A. Rendle Short, for compiling the volume include Dr. J. H Anderson, Dr. R G. Bannerman, Dr. Joseph Blomfield, Dr. Charles Corfield, Dr. Ivor J. Davies, Dr Henry Devine, Mr. Norman M. Dott, Dr. F. W. Eurich, the late Dr W. E. Fothergill, Sir Henry Gauvain, Dr. A. G Gibson, Dr. A. M. H. Gray, Major V. B Green-Armytage, Prof. E. W. Hey Groves, Col. L W. Harrison, Dr. C. Thurstan Holland, Dr. Robert Hutchison, Mr. Geoffrey Jefferson, Lt-Col. A. E J. Lister, Mr. J. P. Lockhart-Mummery, Dr. Hugh MacLean, Dr. Reginald Miller, Dr. Joseph Priestley, Sir James Purves-Stewart, Sir Leonard Rogers, Dr. J. D. Rolleston, Dr W. G. Savage, Dr. Edmund I. Spriggs, Sir John Thomson-Walker, Sir W I de Courcy Wheeler, Mr A. J M Wright, and Dr William H. Wynn. The editors in a brief introduction stress the developments which they consider of especial importance and indicate the direction of progress in various subjects In some of the surgical articles mention is made of the increasing use of electrothermic methods of cutting tissues Notable among the medical articles are those on gastric and duodenal ulcer and on gall-bladder disease. Venereal diseases receive full discussion on modern lines; the surgery of the kidney is exhaustively dealt with. while the interest in phototherapy is reflected in the considerable space devoted to this subject; some of the plates in this last-named section could have been spared, since the general benefit of heliotherapy is no longer in any doubt. A note on alopecia areata records good results from the use of carbon dioxide snow; it is claimed by Lortat-Jacob that even in old-standing cases the hair starts to grow again after three or four applications given within three weeks, the patches being rubbed with a blunt pencil of snow until freezing is complete It is refreshing to find from time to time sandwiched between articles which give detailed summaries of recent work the leisurely reflections of Dr. Joseph Priestley, whose short essays give an admirable picture of the trend of thought in the subjects he discusses Altogether this year's "Medical Annual." while it has no outstanding discovery to expound, is one of the best that has appeared.

ST JOHN'S DERMATOLOGICAL SOCIETY.

A MEETING of this Society was held on April 27th, with Dr W S FOX, the President, in the chair

Dr H G ADAMSON opened a discussion on the

Treatment of Some Common Skin Affections

by pointing out how the dermatologist might, from the standpoint of his special subject, attack almost all the problems of medicine and pathology He said that, without wishing to decry the search for new or more scientific remedies, he felt certain that successful treatment often depended more upon skill in applying a few well-known remedies than in the random employment of new methods, many of which had in recent years proved disappointing Vaccinotherapy, except for acute staphylococcal infections, had not helped the dermatologist much Lupus vulgaris could not be cured with tuberculin The most valuable new addition was X ray treatment, but even this was empirical

Passing to special conditions, Dr Adamson expressed the opinion that most eczemas owed their origin to some local irritant, while all were aggravated or kept up by scratching, friction of the clothes, special occupation, or inappropriate treatment Protection from external irritants was the essential treatment for eczema A common protection was zinc oxide paste, which should be thickly spread on pieces of open-wove bandage, applied like plaster and firmly bound on Lint must not be used and the covering layer of wool must be as thin as possible Twice daily the dressing was wiped off very gently with liquid paraffin and renewed "Thorough cleaning up" of affected areas often delayed cure The advantages of tar, of sulphur in seborrhœic eczema, and of small doses of X rays in all cases were well known When progress was slow lenigallol, 15 gr, might usefully be added to each ounce of the zinc paste He had no faith in internal remedies or dieting

Psoriasis and Lichen Planus.

Probably all dermatologists used the same methods for psoriasis—mild mercury ointments, tar, chrysarobin, arsenic, &c —but an important point was that the ointment should be well rubbed in Some cases would get well with a simple vaseline if only it were painstakingly applied Dr Adamson's favourite application was a paraffin ointment containing 10 gr. of hydrarg ammon chlor and 1 drachm of liquor picis carb to the ounce Much of its efficacy seemed to be due to the hard paraffin base A useful remedy for psoriasis of the scalp was undiluted liq picis carb rubbed in with a cheap pastebrush with its bristles cut short Salicylates or salicin internally had a beneficial controlling effect in cases of acute psoriasis with widespread small-pattern eruption Salicylates also cut short the duration of pityriasis rosea If the patient would submit to a thorough course of treatment in bed for at least a month, chrysarobin would generally clear up extensive and obstinate cases of psoriasis

The only known ætiological feature in lichen planus suggesting a line of treatment was worry or overwork, and of all methods the rest cure was the best Many cases cleared up very quickly with rest in bed, but for more chronic cases this must be combined with local treatments, of which the best was daily painting with silver nitrate, 10 gr in one ounce of spirit of nitrous æther

Impetigo Contagiosa, Acne, and Pemphigus

In the majority of patients impetigo ran its course in three weeks, whatever treatment was given, but in more persistent cases the period of recovery was generally shortened by daily mopping with silver nitrate solution Three or four applications of ultra-violet light would usually cure impetigo at any stage X rays, which made this condition spread more rapidly, were very efficacious for acne when carefully applied Patients should be told never to touch the face, squeezing and picking the spots kept up the eruption and caused excoriations Pemphigus in children was generally cured by confinement to bed, this measure was helpful with adults, as also was a daily bath Instead of an ointment, paraffin No 7, applied as for burns, added to the patient's comfort Small doses of tincture of opium benefited the nervous system and had a curative effect

Some well-known Remedies

Hot boric or saline fomentations were valuable in furunculosis, impetigo, septic wounds, and crusted lupus, but they were often used wrongly They must be large, hot, and changed every 10 or 15 minutes for an hour or two, alternating with dry dressing Many diseases of the skin were best treated in bed where continuous treatment could be given and constant irritation of the skin avoided Rest in bed was the only thing that would lead to marked improvement in general pruritus, pemphigus, lichen planus, and lupus erythematosus General pruritus without obvious cause would often disappear completely after a few days in bed The good results in lupus erythematosus might perhaps be due to non-exposure to light and changes of temperature. Pure carbolic acid applied to a perfectly dry skin had no immediate effect, and if wiped off with methylated spirit had no caustic action At the worst its caustic action was not deep Its desquamating power might be used for destroying freckles and for pruritus The acid was painted on to the freckle with a pointed match-stick and the pigment was permanently removed without scarring Senile warts could be removed by pressing the acid on firmly with a piece of wool held in forceps

Pruritus

A common form of pruritus, occurring only in women, was associated with one or more sharply-circumscribed patches of lichenification at the nape of the neck A pastille dose of X rays would usually stop the itching, but removed the hair Carbolic acid swabbing was quite as effective In most cases of pruritus ani or vulvæ there were found either patches of lichenification due to rubbing, or else radiating fine shallow fissures, or both together The fissures could be effectively healed by touching with a finely-pointed match dipped in pure carbolic acid The lichenification patches should be mopped with silver nitrate in spirit ætheris nitrosi Immediate relief followed, but permanent cure was ensured by an application of X rays, five-sixths of a pastille dose, repeated after six weeks Another use for carbolic acid was on a tiny shred of wool which, pushed between the nail fold and the nail, would quickly cure onychia

Uses of Silver Nitrate

Tincture of iodine might well be supplanted by 15 gr. of silver nitrate in an ounce of spirit of nitrous ether Iodine produced local inflammation which often masked the original complaint and might start a widespread dermatitis or even pemphigus The nitrate was efficient in tinea circinata and cruris, and eczematoid ringworm of the feet Often one or two thorough swabbings would cure a tinea cruris of long standing, and it was useful in any superficial microbic infection of the skin It was best applied by means of a small swab of wool held in forceps and well pressed into the affected area It had a well-known value in obstinate and infantile eczemas The relief it afforded to itching made it useful in lichenification and senile pruritus Lapis divinus, a mixture of copper sulphate, potassium nitrate, alum, and camphor, fused on the end of a probe, was an excellent remedy for fissures in the nostril and for acne pustules For electrolysis of hairs the most useful needle was a smooth dental "nerve broche," which did its work without leaving a scar Another useful tip was to place a strip of zinc oxide plaster round the fore finger of the left hand so that the hairs collected on its sticky surface Such little cosmetic operations in detail The complications of gonorrhœa in both sexes are fully discussed. The chapter on gonococcal vulvo-vaginitis in children is good, and the metastatic complications are not neglected. In this connexion treatment of the original focus by diathermy deserves fuller discussion than it receives in two lines on p 489 In the treatment of gonorrhœa of pregnancy Mr Lees says that tampons should not be inserted in the fornices or vagina as they tend to produce abortion There may be a difference of opinion as to the value of tamponage, but in our experience fear of producing abortion would not be a contra-indication Has abortion really been caused in Edinburgh by this treatment or is Mr. Lees quoting a traditional belief? The book concludes with an admirable pharmacopœia covering every possible medication that may be needed in the whole range of treatment of syphilis or gonorrhœa.

Mr Lees's work may be recommended for its practical common sense no less than for its medical and scientific value.

Anatomy of the Central Nervous System.

Anatomie Topographique du Système Nerveux Central By Georges Guillain, Professor of Clinical Neurology, Faculty of Medicine of Paris, and Ivan Bertrand, Director of the Laboratory of Pathological Anatomy, Clinique of Neurology, Faculty of Medicine Paris Paris · Masson et Cie 1926 With 60 original plates Pp 322 F 80

Following the best traditions of the French school of neurology, the authors of this handsome atlas of neural anatomy rely for their hope of its practical usefulness on the necessity of pursuing the clinico-anatomical method in neurological instruction, a method in which they express their profound belief Correlation of clinical phenomena with pathological findings has always been advocated in France as the ideal procedure if medicine is to advance, and pathology has its basis in anatomy. Leaving aside neurophysiology, and omitting all unnecessary application to clinical cases as being outside their immediate purpose, they have produced an atlas of pure anatomy, both macroscopical and microscopical, which is intended for the student of neurology Anatomical details, so far from being minimised, are intentionally stressed, and accurately tabulated, in a series of 60 beautiful plates reproduced from original photographs and drawings, which as far as clearness is concerned leave nothing to be desired With this guide at hand the student will find his way through the complexities of neuro-anatomy without difficulty. The text is simple and lucid, the arrangement logical; all the volume lacks is a decent index.

Taken as a whole, this new topographical atlas of the anatomy of the nervous system reflects the greatest credit on both authors and publishers, and will at once find its sphere of practical value in laboratory and study.

Peripheral Palsies

Die peripherischen Lähmungen; Diagnostik, Untersuchungstechnik, Prognostik, und Therapie By Prof Dr Toby Cohn, Berlin Berlin and Vienna Urban and Schwarzenberg 1927. With 64 illustrations. Pp. 320. Mk.18

This book on peripheral palsies, motor and sensory, cranial and somatic, reaches a high level of attainment It is about equally divided into a general part, containing full descriptions of methods of examination, ætiology, pathological anatomy, prognosis, and treatment and a special part, in which cranial and peripheral nerves are taken seriatim and their symptomatology minutely investigated. Due attention is given to the rarities as well as to the commonplaces, and this, together with a good index, a fine bibliography, and satisfying illustrations, makes it a volume well worth adding to the neurologist's library The fact that new diagrams of the motor points on the skeletal muscles take the place of those of Erb, which have done duty for half a century, is of itself a comfort to the reviewer.

Detailed criticism of the work is rather out of place, seeing that it of necessity embodies a mass of anatomical and clinical data through which one can scarcely hunt for possible errors or other sins, positive or negative; it is for reference more than for systematic perusal We note in passing that the author inclines to the view of a sympathetic origin for some types of pain—e.g, that of causalgia—without as we think supplying adequate proof of the theory or realising sufficiently the equivocal results of some operations on periarterial plexuses That cervical rib may occasion at one time a median, at the other an ulnar paralysis is duly recognised, but the partial character of the former is not sufficiently insisted on or illustrated. On this point differential diagnosis to some extent at least must depend

The Red Nucleus

Die Bedeutung der roten Kerne und des übrigen Mittelhirns für Muskeltonus, Körperstellung und Labyrinthreflexe By Dr. G. G. J. Rademaker, Utrecht Translated into German by Dr E Le Blanc, privatdozent at the University of Hamburg Berlin · Julius Springer. 1926 With 212 illustrations Pp 340. M 27

Dr. Rademaker's masterly investigations of the functions of the red nucleus and the mesencephalon generally were published in Dutch and the opinion was widely expressed that their appearance in another language somewhat more accessible to the average student of the nervous system was a desideratum. Hence the publication of the monograph in a German garb It has already taken its place as one of the outstanding contributions to neurology of recent years, and as exemplifying in a striking fashion the value of the methods of the experimentalist. The subject is highly technical and possibly of somewhat limited interest, but its appeal to the specialist is unmistakable. Very briefly, the purpose of the research was to define and determine the anatomical centres and tracts responsible for the activities of some of the reflex mechanisms studied and described by Prof. Dr. R Magnus In this effort the author has succeeded very materially, and his conclusions have been accepted by other workers at the same problems It is impracticable to give an adequate resume of these in small space, and we shall be content to recommend its careful study to all who are interested in the minutiæ of midbrain anatomy and physiology.

Life and Evolution.

By William Tibbles, LL D, L R C.P., M R C S. London: John Bale, Sons and Danielsson, Ltd. 1927. Pp 233. 6s.

Dr. Tibbles evidently has much wider interests than are indicated in that useful book "Foods · their Origin, Composition, and Manufacture," and he gives here revised versions of a number of popular addresses which range over a large field of soluble and insoluble problems The first three chapters are on life, matter and force and cause and effect. and their general argument is that the materialistic interpretation of life is incomplete and unsatisfying and that the cause of the world as we know it is God The last five chapters are more direct and give an excellent elementary account of evolution especially the evolution of man and of the English man in particular. The tale he tells is necessarily rather a dogmatic version of many matters on which there is no really certain knowledge, but it is straightforward, comprehensive, and interesting, and he takes the cheerful view that the study of the past is meant to help us solve the future The whole forms a book which should be useful and stimulating to lay readers; it provides also some good outlines for popular lectures

THE SLIT LAMP

An Illustrated Guide to the Slit Lamp By T. HARRISON BUTLER M A , D M Oxon , late Radcliffe Travelling Fellow of the University of Oxford , Honorary Ophthalmic Surgeon to the Coventry and Warwickshire Hospital London Humphrey Milford, Oxford University Press. 1927 Pp 144 30*s*

THE use of the slit-lamp in conjunction with the corneal microscope is the most important advance in the technique of ophthalmological diagnosis which we have seen in recent years To acquire familiarity with it, however, needs time and special teaching which it is not too easy to obtain Mr Harrison Butler went to Switzerland and obtained his teaching from Prof Vogt, whom he regards as the greatest authority on this subject, having created what amounts to a new science

This book is the outcome of Prof Vogt's teaching and of Mr Butler's own work during the last three or four years Those who have access to an instrument and are prepared to give up the time necessary to acquire familiarity with it will undoubtedly find this book an enormous assistance It is copiously illustrated by over 147 figures and five coloured plates, some diagrammatic, but many of them illustrating appearances which Mr Butler has himself observed So far it is the crystalline lens on whose structure the slit-lamp has revealed the most striking new knowledge By the use of the " narrow beam " we are enabled to see a series of highly illuminated sagittal sections, and as the different layers have different refractive indices some of them show brighter than others In this way various regions are mapped out By the use of the " broad beam " and focusing, the various surfaces can be examined in a detail never before approximated to The practical importance of the slit-lamp in diagnosis has as yet not received any wide general recognition The chief practical points on which Mr Butler lays stress are (1) the estimation of the depth of opacities in the cornea, (2) the diagnosis of the nature of " K P " spots, (3) the detection of the presence of solid flakes in the aqueous and retrolental space, a matter which may be of decisive importance in the diagnosis of sympathetic ophthalmia , and (4) in the exact estimation of the situation of opacities in the lens From the point of view of medical jurisprudence he shows by actual examples how important slit-lamp evidence may be, for instance, in distinguishing between recent and old opacities in cornea and lens

It is a book which will be very highly valued by all users of the slit-lamp

X RAYS PAST AND PRESENT

By V. E PULLEN and W J WILTSHIRE London. Ernest Benn, Ltd 1927 Pp 229 12*s*. 6*d*

IN a preface the authors state that they have written this book with no ambition of producing a scientific treatise, but with the object of telling the story of X rays by means of a panoramic sketch for the benefit of the interested layman The result of their labours is the clearest and most readable exposition of the subject that we have yet seen A brief but lucid historical section, occupying two chapters, explains the various stages in knowledge that led up to the discovery of X rays This discovery was in no sense accidental, but inevitable, since many observers were actually producing rays which they had not recognised as the source of disconcerting phenomena which they could not interpret The next chapters deal with the nature of X rays, the researches which culminated in the discovery and weighing of the electron, and the brilliant work of J J Thomson, Rutherford, the Braggs, Moseley, and many others Incidentally the large share of the meteoric advance in knowledge, due to these and other English physicists, will strike every reader Other chapters follow, brief but adequate, on X rays and crystals, X ray spectroscopy, and on various applications of X rays in science and industry. The book well fulfils the purpose for which it was written

The authors have succeeded in explaining nearly all the difficulties in such simple language that they have not had to resort to the formulæ which are the language of the physicist, and the stumbling-block of the layman They have succeeded in conveying to the reader their own infectious keenness and the element of romance that goes hand in hand with all true research

DISEASES OF BONES AND JOINTS

Études sur les Affections des Os et des Articulations (Colonne Vertebrale exceptée) BY ANDRÉ LERI, Professeur agrégé à la Faculté de Médecine de Paris, Médecin de l'Hôpital de la Charité Paris Masson et Cie 1926 Pp 460 Fr 58

THIS book is a sequel to that by the same author on affections of the vertebral column, which was noticed in our issue of Jan 15th, 1927 Like that work it consists of a number of short articles on affections of the bones and joints, and they seem to be reprints of contributions by the author alone or in collaboration with other well-known authorities to various publications

It is difficult adequately to sum up a book of this kind because of the great number of subjects ; 58 communications are here reproduced However, those who are seeking records of rare conditions of bone and joint disease will find it of value, and perhaps also those who would study different points of view of certain diseases The author in his introduction disclaims any intention of supplying a précis or handbook for the student Articles are grouped together under the headings of I Diseases of Bones, and II Diseases of Joints The first part is divided into diseases of development and malformation, and acquired diseases of bone, while the second deals with rheumatism and arthritis and their pathogenesis and treatment It will thus be seen that tuberculosis of bones and joints is excluded The most important articles are those on rickets and on Paget's disease The section on treatment of chronic rheumatic affections is interesting ; the author thinks that the good effect in these maladies of thermal springs and mud is due to radioactivity Since 1921 he has been following the suggestion of Prof Gabriel Petit and using intramuscular injections of bromide of thorium X , the dose being regulated by the radio-activity of the drug, as compared with that of crystallised radium bromide This treatment does not affect bony deformity, but relieves pain, and this relief puts an end to reflex contraction and allows physiotherapeutic measures to be applied The results obtained were encouraging The book is illustrated with 128 figures

VENEREAL DISEASES

Diagnosis and Treatment of Venereal Diseases By DAVID LEES, D S O , M A , M B , F R C S , Surgeon in Charge of Venereal Diseases, Royal Infirmary, Edinburgh Edinburgh E and S Livingstone 1927 With 87 plates Pp 605 15*s*

IN this new work Mr Lees has brought together in a readable form the latest ideas and technique in the diagnosis and treatment of the three venereal diseases In the first part of the book syphilis is fully considered, and the recognised pathological tests which may be employed in its diagnosis are described Treatment is clearly and fully discussed, all the modern drugs and their mode of application being given in detail, and tables of treatment of the different stages of syphilis are included Some of the plates in this section will prove of great value, particularly to the student or young practitioner who gets little chance of observing syphilitic rashes owing to their rapid disappearance under modern therapy.

In the second part gonorrhœa is dealt with most thoroughly, and treatment is here also described

THE LANCET.

NDON SATURDAY, MAY 7, 1927

JEEN CHARLOTTE'S HOSPITAL

iblish in another column a weighty manifesto obstetric surgeons who, under the title of the Mothers," plead with the public for a of a million of money for the erection of new s to provide more beds and greater facilities ntific training in connexion with Queen e's Hospital As everyone knows, the y from childbirth is still deplorable, and the nt chart, which appears in the manifesto, at a glance that this mortality has shared in the reduced mortality among women from es or in the reduced infant mortality which n an increasingly marked feature of the vital 's of the present century Many of these il deaths are undoubtedly preventable, and n addition to the beds at a centre like Queen te's Hospital would mean a great deal, far ould be meant by larger opportunities for the of medical students and of student midwives whole science of midwifery and obstetrics is admitted that medical students are still d in these subjects, as far as the metropolitan schools are concerned in a desultory manner, must remain the case, although the strenuous of many teachers and the improvement in have recently been apparent, as long as hospital ions remain so imperfect There is no doubt edical students do not obtain the same oppor-'s for clinical education in midwifery and rics that they do in other branches of medicine, absence of sufficient maternity wards to which udents could have access hampers them and nstructors alike

he study of midwifery and obstetrics, as it now s in this country, there are things of the highest ance which require general consideration— which affect the public and the medical ion alike There are large factors inherent in actice of to day which affect throughout the ent of difficult labour and their significance is ly felt They have been set out with detailed ations by a group of authorities in an Extra r of THE LANCET[1] some two years ago and the n teaching of all was that the practice of mid-now means, above all things, the avoidance of and the early recognition of abnormal con-notification of sepsis becoming necessary when line of defence, prevention, has been breached t sufficiently considered that the medical man, face to face with emergency, is little aided by the knowledge that the situation need not have arrived if due preventive methods had been taken? And the only way in which the knowledge of what preliminary precautions ought to be observed can become the general property of practitioners or midwives is to offer opportunities for obstetrical consultations, where apposite bacteriological examinations have been arranged for, where the necessary number of maternity beds can be found, and where a system of antenatal care can be organised as a model "The antenatal care of pregnant women has been demonstrated to be one of the most valuable of all forms of preventive medicine," says the surgical manifesto "It must be considered as the most important modern development of obstetrics, and one of its chief activities Failure to provide facilities for antenatal treatment is one of the most conspicuous pieces of evidence that maternity hospitals are not keeping pace with the movement, and experience emphasises more and more strongly the vital need of preventive methods" These words furnish the reason why so many women still die in childbirth or suffer ills arising from the discharge of a natural function, for it must be remembered that, on the top of the maternal mortality, a large percentage of all the conditions for which women seek relief either in hospital or in private practice are definitely connected with the ordeal of childbirth More maternity beds are urgently required in order that the education of those concerned in the actual care of the women should be properly conducted, and that the teachings of modern science should become part and parcel of routine practice

The appeal issued by Queen Charlotte's Hospital demands the public help in a direction where all can appreciate its urgency and the authorities in asking for £250,000 to be used for the construction of new buildings and for the promotion of research are able to show, not only the necessity for finding the money, but the proof that the money, when found, can be immediately and definitely employed for its objects With the capital sum which it pleads for the hospital will provide modern wards, fully equipped, for another 75 beds, single private rooms for middle-class paying patients, completely equipped pathological laboratories, special facilities for research into childbirth fever, and the machinery for training more doctors, students, and nurses It is proposed, we learn, that the money should be shared almost equally by endowment, and building and equipment As the freehold of the adjoining ground is already owned by the hospital, no time will be wasted in the expensive and wearisome task of securing a site Those who give promptly—and there should be many, for the appeal is to manifold sympathy—will see a prompt result

◆

LOOKING AT THE SUN

IN clear weather it is only at sunrise and at sunset that we can with comfort look directly at the sun with the unprotected eye At these times the great distance of atmosphere through which the sun's rays have to travel before reaching our eyes serves to diminish their intensity to a point within the limit of safety. When the sun is high the eyes are protected from glare by the lid and brow, and if we attempt to look up at the sun's disc we are dazzled and instantly turn our eyes away If in spite of being dazzled we persist in looking, we run a great risk

This risk, as Sir ARNOLD LAWSON and Mr A L WHITEHEAD pointed out in an article in our columns last week (page 949), is one which is likely to be taken

ULTRA-VIOLET THERAPY

Ultra-violet Radiation and Actinotherapy Second edition By ELEANOR H RUSSELL, M D., B S Durh, and W KERR RUSSELL, M D, B S Durh, Hon Actinotherapist Sun-ray Clinic, Newcastle-on-Tyne With forewords by Sir OLIVER LODGE F R S, D Sc, LL D, and SYDNEY WALTON, C B E, M A, B Litt Edinburgh E and S Livingstone 1927 Pp 429 15*s*

ENLARGED from 262 to 429 pages, the authors' second edition follows the same general lines as the first The chief enlargement of the book appears to be in those sections devoted to the technique of therapeutic work and in the account of the various ailments for which ultra-violet radiation is useful Illustrations are abundant throughout; no less than 65 are to be found in the two chapters devoted to a description of the various artificial sources of ultra-violet radiation Readers requiring information on the technical or medical side of ultra-violet therapy will find what they want in this book

---

Les Radiations Lumineuses en Physiologie, et en Therapeutique By A-C GUILLAUME Paris Masson et Cie 1927 Pp 515

THIS book is unusual The author warns the reader in his preface that he will here find no practical guide to actinotherapy nor manual on the subject, but rather a series of experimental studies bearing upon actinotherapy from different aspects, these studies take the reader into various fields, in some of which the way has sometimes been clearly found by well-designed experiments in others there are still no signposts to give confidence to the casual wanderer

Dr Guillaume's approach to the subject is from the experimental side; he disclaims any special knowledge of actinotherapy He is, in fact, more concerned with the setting of the stage than with the acting upon it, and indeed he adopts a critical attitude on what the actors choose for their play However a discussion as to what diseases should or should not be treated by actinotherapy is included in one of the final chapters The chapters on the local and generalised action on the skin and body of various forms of radiation are exceedingly interesting, and the phenomena of sensitisation and of protection are fully described A whole chapter is devoted to the fluorescence of tissues and their examination under beams of pure ultra-violet radiation

The scientific scope of the book is wide, and it will be read with profit by many who have no special interest in the particular form of therapy that is considered No reader can fail to be impressed with the efforts which are being made to elucidate some of the complexities inherent to the study of radiation in its effects upon living things

---

JOURNALS

QUARTERLY JOURNAL OF MEDICINE —The April number contains the following articles · An Attempt at the Clinical Classification of Premature Ventricular Systoles, by Geoffrey Bourne Twenty-eight cases were examined in which premature ventricular systoles occurred fairly frequently The effects of exercise, amyl nitrite, and atropine upon their occurrence, in association with their relationship to heart disease and heart failure were investigated The results showed, amongst other things, that standing increases the number of premature beats, exercise augments their occurrence after the deceleration period in cases with arterio-sclerosis or with coronary disease, the reverse holding good for normal or rheumatic hearts —Observations upon the Circulation-rate in Man by the Ethyl Iodide Method by H Whitridge Davies and A Rae Gilchrist In 1925 Henderson and Haggard in America published a method for estimating the circulation-rate in man by inhalation of ethyl iodide It can be rapidly effected and causes no discomfort to the subject In the present paper the authors describe certain modifications of the technique, and the results of 118 observations on 18 individuals under varying conditions of posture, temperature, activity and metabolism —Fractional Analysis of the Gastric Contents: a Preliminary Note on the Variation of the Free Hydrochloric Acid and Total Chlorides in the Upper and Lower Parts of the Stomach, by Robert J Duthie Several observers have noted the variations obtained in fractional gastric analysis in the same individual on different occasions The author here uses a double stomach-tube, the orifices being 8 inches apart This was swallowed, and samples could then be obtained simultaneously from the pyloric and cardiac regions of the stomach The position of the tubes was controlled by X ray examination In the three cases examined differences in the free acid and total chlorides were found in the upper and lower regions of the stomach during the digestive cycle —An Investigation of Gastric Function in Chronic Arthritis and Fibrositis, by S Miller and F B Smith Two hundred and fifty cases of chronic arthritis, in whom the disease was still active, were investigated by means of fractional test-meals and examination of the fæces and urine for streptococci Although achlorhydria and hypochlorhydria were found to occur five times more frequently than in health, yet their incidence was only slightly greater than that found by other observers in a series of other diseases A similar slight preponderance of streptococci in the fæces, as compared with those obtained in other diseases, was also found The diminished acidity is not therefore considered to be a primary factor in the ætiology of the disease —The Effect of Mineral Acid in Acid-Base Regulation in Health and in Nephritis, by Geoffry C Linder The permanent readjustment of the acid-base equilibrium in the blood depends upon the action of the kidneys, and the author describes observations on the power of the kidneys in this respect in varying states of health and disease Dilute hydrochloric acid was given to four normal people and to six patients with nephritis for periods of two to four days, and the changes in the blood and urine were studied The results obtained are detailed in this paper, and in two patients whose renal function was greatly impaired severe acidosis was produced —Heredity in Simple Goitre, by W Russell Brain In a series of six families there were 26 cases of simple goitre, and in two of these families cases recurred in four successive generations In another series of five families 12 cases of simple goitre occurred, associated with congenital deaf-mutism A hereditary predisposition does appear to be a factor in the ætiology of simple goitre in some cases, and the incidence of goitre is further considered in relation to Mendelian laws —Radium and the Blood Cholesterol, by Charles E Brunton The blood cholesterol in a series of patients suffering from cancer was found to be about normal No definite variation was found in the blood cholesterol of cancer patients after treatment by diathermy or by radon —The Clinical Duration of Saccular Aortic Aneurysm in British-born Subjects, by G H Colt Seven hundred and seven cases of saccular aortic aneurysm have been collected from the literature, and their clinical duration noted from the first date of the longest recorded symptom The cases have been considered statistically, and it is hoped that the graphs prepared will be of value for prognosis —The Effect of Administration of Parathyroid on the Serum Calcium by C P Stewart and G H Percival The serum calcium was estimated in 11 cases before, during, and after the administration of parathyroid (Martindale) In every case the calcium was stationary, and normal or slightly above normal before the parathyroid was given, but rose as the result of the parathyroid administration —The journal concludes with an account of the twentieth annual general meeting of the Association of Physicians of Great Britain and Ireland, held at Newcastle-upon-Tyne in May, 1926

European medicine and a great number of journals and pamphlets All the six libraries described in the Rockefeller report are, indeed, conducted with the highest kind of medical knowledge in view and on the most advanced modern principles

The medical profession is perhaps better supplied than any other with exhaustive catalogues and library helps of every kind In the fine library of the Harvard Medical School there are some 45,000 volumes, over 100,000 pamphlets, and the number of current periodicals is over 400. But the student is not left at sea among all this, for "the attendants in all the rooms answer all inquiries and try their utmost to supply the information desired" The librarians, Dr Elliott P Joslin and Frances Whitman, "take pleasure in giving assistance" We can well believe it, and the same may be said of medical librarians all the world over The library of the Washington School of Medicine, St Louis, under the skilled management of Miss Etta Lawrence, now numbers well over 33,000 volumes, having risen from a nucleus of 3000 volumes in 1910 Unlike most very modern collections, this admirable library, "classed with the best libraries of medical schools," possesses antiquities in the shape of the Beaumont Collections These consist chiefly of the note-books in which for years Dr. William Beaumont, the pioneer American physiologist who was also F R C S England, set down his observations of the workings of the gastric juice through the fistula in the abdomen of Alexis St Martin A library which promises very well, though it is at present small, is that of the Queen's University, Kingston, Ontario It forms part of the large university library of 175,000 volumes At McGill University the medical collection is extensive, amounting to some 60,000 volumes It is more than a century old, having been founded in 1823. In 1907 the Osler Library was erected, and here are housed the 7000 odd volumes, which it was the life-work of that fine bibliophile, Sir William Osler, to collect. The Osler Library has a noble appearance worthy of him whom it commemorates The Rockefeller Foundation has issued the report in pamphlet form, as the sixth instalment of a larger work, which will doubtless contain descriptions of the famous medical libraries of London and of the Surgeon-General's Library at Washington, as well as of those of the Continent of Europe

◆

ADDITIONAL INSURANCE BENEFITS

THERE is gratifying evidence that the scheme of the Insurance Acts is now being developed along preventive lines Last month, in reply to a question by Sir John Power in the House of Commons, the Minister of Health gave some interesting figures showing the extent of additional benefits granted to insured persons during the year 1926 (THE LANCET, April 23rd, p 901) During this twelvemonth a sum of more than one million pounds was expended on dental treatment and nearly a quarter of a million on treatment in hospitals Much of this dental treatment is of a preventive nature and, along with the medical inspection of school-children and dental treatment at school clinics, it cannot fail to react in the course of time on the incidence of sickness The amount spent on treatment in hospitals and the £7000 on provision of nurses might well have been much larger, for both of these are essential services for the restoration of the sick worker to normal health. No information was given as to the amount of additional benefit given by way of increase in the ordinary cash benefits, and so no material is available to judge what relation this outlay bears to the one-and-a-half millions spent on specified additional benefits, but it is to be hoped that the latter fund will go on increasing, when there will soon be manifest some improvement in the efficiency of the workers and some reduction in the time lost from incapacity The figures given by the Minister of Health are evidence that the problem of preventing sickness is being seriously tackled by the approved societies

Annotations.

"Ne quid nimis"

THE BRINE BATHS OF DROITWICH

THE ancient township of Droitwich lies in a hollow of the beautiful Worcestershire hills, and 200 feet beneath it is the inexhaustible bed of salt which has provided brine for commercial and therapeutic use since Roman times The water, which used to well up to the surface but now has to be pumped, is unique among the mineral springs of the world in its concentration—ten times stronger than sea-water, 40 per cent stronger than the waters of the Dead Sea, and among mineral springs approached only by those of Rheinfelden and Bex in Switzerland The water is only available on the spot, for Droitwich believes, with much show of reason, that the full effects of the brine cannot be obtained from redissolving the evaporated salt, and that the high degree of radio-activity present in the fresh brine would be dissipated by evaporation or during long transit There is little, if any, accurate knowledge as to the precise action of brine baths on the various systems of the body. Salt-water baths are reputed to have a much more stimulant effect than have ordinary baths of the same temperature, and Droitwich repeats in season (and perhaps out of season) the story of the rediscovery of the stimulating properties of the brine when the contents of an evaporation pan were used in emergency for a collapsed cholera patient a century ago. The influence of salt water on metabolism has been the subject of much experiment and discussion, but, as Dr. Huggard said 20 years ago,[1] no very positive conclusions have been obtained, and the same is largely true at the present time Testimony to the chemical activity of the brine is borne by the corroded taps and discoloured walls of the old baths, which the new installation completely masks by its vulcanite fittings and vitrolite panels The buoyancy of the water is such that the immersed body or limb is completely supported, so that stiff and partly paralysed muscles are enabled to move on their own initiative with little expenditure of energy Active movement of this kind is a unique feature of the brine bath, and war-time experience not only suggested its great utility but the possibility of its taking the place to a large extent of massage and passive movement The doctors of Droitwich are all busy general practitioners, with little time to devote to the why or the how of the good results of which they are daily witness, and at his visit last week, recorded on another page, Mr Neville Chamberlain gently chid them for an omission which may be preventing Droitwich from being useful on the scale which it merits Mr Chamberlain was careful to explain that he was speaking as one of the trustees of the Corbett Estate, to which the bathing establishments belong, and not as Minister of Health , but the local medical profession will do well to take his words to heart and in the course of time provide good evidence for the faith which is in them There should, at all events, be no lack of occupation for a full-time biochemist at Droitwich

SPLANCHNIC ANALGESIA

SPLANCHNIC analgesia has been in use since 1914, when M Kappis first reported on it at the Surgical Congress at Berlin Since then H Braun (1919) and G Labat have made important additions to the literature of the subject In our own columns[2] a record of 91 cases has been published by O S Hillman and R E Apperley There has been time, therefore, for the technique of the method to be systematically and thoroughly established and for its thoughtlessly on June 29th next when many people in North Wales and Northern England are hoping to enjoy the only chance in their lives of seeing the corona of the sun surrounding the black disc of the moon Even after any ordinary partial obscuration of the sun a few cases of "eclipse blindness" come under the observation of ophthalmic surgeons The number may be very much larger as a result of the widely advertised total eclipse of June, unless the danger be equally widely advertised The visible and infra red rays from the sun passing for the most part unchanged through the cornea and lens are focused approximately on some part of the retina whenever the eye is at rest and the sun within the field of vision Reaching the retina, these rays pass through its superficial layers without doing any harm until they reach the pigmented epithelial cells at the back, where they are degenerated into heat, which gives rise to a thermal lesion (an ordinary burn) spreading inwards to the retinal tissues and outwards to the choroidal vessels Fixation of the sun's image on any peripheral part of the retina must, however, be a very rare occurrence, and a point lesion, if it should occur, would probably give rise to no inconvenience But at the macula or central spot of distinct vision the case is quite otherwise Here in the normal eye the rays are accurately focused and at a moment of keen interest discretion may be thrown away and fixation of the sun's image occur The macula is the most vulnerable part of the retina, for at this spot the retina is thinnest, all the layers having nearly disappeared except the cones and the pigmented epithelium, while there are no blood-vessels which supply the central spot direct and might help to distribute the heat Hence, if the warning sensation of dazzle is disregarded, a thermic lesion may result, leading to permanent damage at the macula, with pigmentary changes which can be seen with the ophthalmoscope, and at the macula even a point lesion will lead to a visible blank in the field of vision It is thus the red and yellow rays from which the retina runs the chief risk The ultra-violet rays, it is true, cause conjunctival trouble and pain, but they are, it seems, largely absorbed by the cornea and the crystalline lens and therefore do not reach the retina in any dangerous quantity except in young children in whom the lens is very transmissible, or in those whose lens has been extracted by operation

[2] THE LANCET, 1925, i , 863

We dwell upon this danger to the unprotected eye by no means because we wish to discourage anyone from seeing what he can of the eclipse, but rather to remind would-be astronomers, and especially all who have the care of children, that the danger is as real as the safeguard is simple All that is necessary for a brief survey of the eclipse is to interpose a piece of smoked glass or of fogged photographic film of such a density that the sun when seen through it is no brighter than the setting orb The photographic film is the safer, as the smoked surface rubs easily off the glass when in use A further refinement in precautionary equipment is described in Sir Arnold Lawson and Mr Whitehead's note Untreated film, they *insist, does not afford sufficient safeguard for* prolonged sun-gazing It may remove the glare, but it does not prevent the ultra-violet burn of the anterior structures of the eye, and they have collaborated in the production of a photographic film so treated that all the short waves are cut out completely, made up in a mask at a price designed to bring it within reach of nearly everyone. We hope these precautions will be brought to the knowledge of all the schools and families in the country and that no one will suffer unwarned from the result of laudable curiosity.

MODERN MEDICAL LIBRARIES

We have drifted far from the days when the bibliothecarius, often a creature of pomp, pedantry *and quaint punctilio*, and always a man of high and curious learning, corresponded on equal terms with a Leibnitz or a Milton Such a man in the late seventeenth century was the famous scholar, Richard Bentley, who was King's librarian at St James's before the days of the British Museum He became Master of Trinity in the year 1700, but may be said to have inaugurated modern classical scholarship when still a librarian The roll of honour of librarians can be vastly extended, for it ranges down to the days of Richard Garnett, Bradshaw of Cambridge, and the present Pope, and numbers in its middle period such names as Lessing and Casanova Doubtless the ancient librarians often dozed aloof, or like erudite silkworms spun their own webs of learning, undisturbed by readers Now all that has been changed The modern librarian is above all things practical Indeed, in his laudable desire to be of use to an ever-growing host of students, as opposed to scholars, he is in danger of specialising in routine This becomes almost painfully manifest when we consider an exhaustive report on "Methods and Problems of Medical Education" recently issued by the Rockefeller Foundation of New York In this bulky pamphlet six medical libraries in different parts of the world, ranging from China to beyond Peru to Brazil and thence to Harvard and the Canadian Universities, have been fully reported upon by modern and able librarians. The general impression that will be left on the mind of any lover of a noble European tradition is that the library of to-day is a sternly efficient machine, an affair of typing, telephony, electricity, but hardly a home of abstruse research and reverent bibliography We hear little in this report of rare and precious works Indeed, in one fine American institution, all books prior to the nineteenth century are referred to by a modern lady librarian as "antiques," and the classification would appear to put John Hunter and his brother, also Sydenham, and many other permanent luminaries, in a fading glow One of the glories of the Rockefeller enterprise is the Library of the Peking Union Medical College Here there are 817 Chinese books, a surprisingly large number when we consider that at the beginning of the nineteenth century only one work on medicine produced in China destined to be of practical utility had come into public notice—there were of course others and more may be yet heard of them The one specially referred to is a translation by Sir George Staunton of Alexander Pearson's work on vaccination, published in Chinese type and illustrations at Canton in 1805 The title was translated for us by the late Sir Robert Douglas, the sinologist, and it ran thus "English recently issued Vaccination Rare-Book" Jenner's discovery appealed to the Chinese almost from the first, and their century long practice of vaccination is in strange contrast with their folk-medicine and the inclusion of tiger's eyes and other strange ingredients in their pharmacy How far the silken-robed figures of Chinese students gliding about the medical library of Peking are bent on modern scientific errands is perhaps matter of legitimate conjecture By all accounts they are serious students and to-day every opportunity is given them for research among some 4300 volumes of only three times or less for treatment. It comes as a surprise to find Dr. McCord saying that he has no hesitation in employing antisyphilitic remedies during pregnancy, for in London their use has been a routine measure for ten years at least, and no reason has been found why the drugs should not be administered if necessary up to the very day of delivery, provided that due attention is paid to the condition of the urine. It is also surprising to find that mercurial inunction has so large a place in his scheme of treatment, since it would be regarded with disfavour by most expectant mothers in this country. Its use may partly account for the poor attendance at the venereal clinic, but this may be inevitable in treating negroes, which is the more reason for using powerful drugs whenever there is an opportunity, especially as syphilitic infection in the negro is said to be more virulent than in white men. There is evidence from other sources, however, that mercurial inunction is in considerable favour in the United States, and of course the results can be excellent when it is given with skill and perseverance. Dr. McCord says that in his service 51 per cent. of stillbirths are due to syphilis—a proportion greatly exceeding that found in any hospital practice in Great Britain and suggesting strongly the need for intensive treatment, and therefore for intensive propaganda among the coloured population. The 300 cases form part of a series of 600 syphilitic pregnancies which he has now investigated, and amongst the 600 about 35 per cent. of the births were premature. Of 320 placentas examined 43·5 per cent. were noted as positive for syphilis.

THE LORD CHIEF JUSTICE ON BUREAUCRACY.

THE Minister of Health has occasionally been criticised for obtaining by means of Acts or Regulations the power of acting as judge to the exclusion of the jurisdiction of the law courts, and for other bureaucratic practices. The Lord Chief Justice has recently commented upon a further example of this tendency. Under Section 67 of the Rating and Valuation Act of 1925 the Minister is given a general power of removing difficulties in bringing this extremely complicated enactment into operation. For this purpose he may make orders of various kinds, and his orders may even modify the provisions of the Act itself "as may appear to the Minister necessary or expedient for carrying the order into effect." These words, remarked Lord Hewart, indicate the high-water mark of legislation of this sort. "Imagination fails to contemplate the extent of the power given to the Minister; he may cut the Gordian knot in any way he pleases." These observations were made during the case of Rex v. the Minister of Health, *ex parte* the Wortley Rural District Council on April 29th. The Court refused to quash one of the orders made by the Minister, but the Lord Chief Justice was not unconscious of the fact that "if the Court had decided to quash the order, the Minister could have attained his object on the following day by making an order under Section 67 'to remove the difficulty.'"

No doubt the Minister can take care of himself, but it is only fair to point out that there is nothing conspicuously novel in this statutory power to remove difficulties by departmental order when any new and intricate legislation is introduced. The power will be found in Section 78 of the National Insurance Act of 1911, in Section 45 of the Unemployment Insurance Act of 1920, and in Section 36 of the Contributory Pensions Act of 1925. It was inevitable that it should occur in a Rating Act which was likely to interfere with all sorts of conditions governing local assessment committees, local officials, and local differential rates—matters depending upon a great variety of local Acts. Moreover every such order under the Rating Act has to be laid forthwith before both Houses of Parliament, and for 28 days thereafter any vigilant Member can move that an address be presented to His Majesty for the annulment and avoidance of the order. Engrossed in his judicial duties, Lord Hewart can hardly be expected to keep an eye upon all Bills or orders laid before the House of Lords. Other critics might be reminded that the best opportunity of checking bureaucracy is to make an effective protest before—and not after—Parliament confers a bureaucratic power. Meanwhile, having had occasion in the past to complain when bureaucratic statutes or regulations seek to deprive the medical profession of its right of appeal to the law courts, we are glad to think that we can reckon upon the support of the Lord Chief Justice when that issue is next raised.

THE HEALTH OF THE ROYAL AIR FORCE.

THE report[1] on the health of the Air Force during 1925 has been recently issued, and is distinguished from those of the other services by the detailed attention it gives to hygienic conditions everywhere, and by the multiplicity of tables showing the age- and trade-incidence of disease amongst the personnel. The average strength in 1925 was 33,028, and the cases of injury and disease amounted to 68·1 and 379·1 per 1000 respectively. The corresponding figures for the previous year were 73 and 391, so that a satisfactory decrease has been recorded; and the same is true for the death-rate, 4·2 per 1000 (last year 4·5), and the invalid-rate, 9·3 per 1000 (last year 9·5). Amongst officers the rate of admission for disease is slightly lower than amongst other ranks, but it is much higher (92·0 per 1000) for injury. Dysentery was most frequent at Hinaidi in Iraq: two-thirds of the cases seem to have been diagnosed in the laboratory, and 10 out of 160 were amœbic. Of enteric fever there were 41 cases, leading to four deaths, and it has been decided that in Iraq inoculation shall in future be done every year, as the protection diminishes. Influenza was more prevalent than in the Army, and especially attacked the apprentices, whose age is 14 to 17. Two primary cases of malaria occurred in England, whilst abroad the number of cases fell to 99·3, the maximum being at Basra: 90 per cent. of the cases seem to have been diagnosed in the laboratory. Pneumonia (1·6 per 1000) was twice as prevalent abroad as at home. Sandfly fever, whose incidence in the forces abroad was 75·5 per 1000, was worst at Mosul but is generally decreasing. Tubercle of lung accounted for 14 cases at home and 13 abroad, the incidence of the disease in the whole force being 0·8 per 1000. The incidence of venereal disease is the lowest yet recorded, showing a further reduction from 22·3 per 1000 in 1923 to 19·9 in 1924. At home the incidence fell from 19·2 to 16·8, and abroad from 30·0 to 27·9. During the same period the primary incidence—viz., the number of new cases per 1000—fell from 16·3 to 15·1. In every 100 infections freshly acquired 83 are gonococcal, 8 syphilitic, and 9 due to soft chancre. The reduction is ascribed to preventive measures further developed this year; even greater success might have been hoped for them. Ulcers of the stomach and duodenum, becoming so frequent in Army and Navy, are not mentioned, but appendicitis caused 6·6 admissions per 1000 men. There were 93 cases of non-specific urethritis. Injuries from athletics formed 88 per cent. of the total injuries; 6·9 per cent. were flying accidents, in which 41 officers and 13 airmen were killed. The total number of casualties in flying accidents was 54 killed and 101 injured, as against 69 killed and 100 injured in 1923. Four deaths by wounds in action occurred in India, where two aeroplanes were shot down. The trade group which had most sickness was that of drivers, with most venereal disease and many injuries, but this group had the fewest admissions for influenza and infections of the upper air passages. All general duty officers were assessed for physical fitness at the end of the year, and 91 per cent. were found fit for full flying duties. In his letter prefatory to the report Air Vice-Marshal David Munro, Director of Medical Services, states that this is the highest figure so far recorded. The chief cause for rejection of recruits value to be fairly well appraised A recent article in *Surgery, Gynecology, and Obstetrics* (April 27th, Part I) summarises no less than 2475 cases and also goes fully into the physiology and the anatomy of the procedure It is obvious that although splanchnic analgesia is of great value in extensive operations within the upper abdomen its use should be limited to these that it should be selected with due consideration, and that its application must be conducted with the greatest care If these conditions are not fulfilled there are fatal pitfalls into which the anæsthetist may blunder, and these are well exemplified in cases quoted in the course of the article to which we refer The accumulated experience of various surgeons and anæsthetists has resulted in showing the advisability of a weak novocaine solution (many prefer ½ per cent to 1 per cent), the absolute necessity of making sure by aspiration before injection that a vein has not been entered, and for making allowances for the constant but temporary lowering of blood pressure which the injections produce It is interesting to notice that whereas in this country the injections are used in conjunction with a light general anæsthesia induced beforehand and maintained throughout, on the continent a general anæsthetic is not employed until called for by symptoms of pain on the part of the patient

TRAFFIC IN WOMEN AND CHILDREN

WHEN the League of Nations was established an article was inserted in the Covenant under which the members of the League undertook (subject to past or future international conventions) to entrust the League with the general supervision over the execution of agreements with regard to the traffic in women and children In June, 1921, an International Conference at Geneva, attended by representatives of 34 countries, made various recommendations It suggested a new draft convention , it proposed to replace the words " White Slave Traffic " with the words " Traffic in Women and Children," so as to make its proceedings apply to all races alike ; it asked that Governments should be invited to make annual reports 'on' the conditions of such traffic , and it requested the League Council to set up an Advisory Council to deal with this subject These proposals were all duly carried into effect The Advisory Council has issued five reports , in 1923 it passed a resolution recommending that, pending the abolition of the system of State regulation, no foreign woman should be employed in the trade of prostitute, or should carry on such trade, in any licensed house , some countries where licensed houses exist are said to have acted upon this recommendation In the same year the Advisory Committee proposed issuing a questionaire to Governments on the topic of the licensed house system and its effect on the traffic , this proposal also was carried out, and resulted in obtaining much useful information Finally the Committee recommended that the Council should appoint a body of experts to investigate conditions This, too, was done with the aid of a generous offer from the American Bureau of Social Hygiene, and Part I of the experts' report is now available It contains material gathered in 28 different countries after interviewing some 6500 persons who were believed able to afford information ; about 5000 of these were connected with commercialised prostitution, and a large number consisted either of prostitutes or *souteneurs* Certain routes of traffic between Western Europe and Central and Southern America were investigated ; inquiries begun in Southern America were extended to Central and Northern America, to countries bordering on the Mediterranean and to certain countries on the Baltic and North Seas The report is a frank document, likely to fulfil its purpose of stirring up public opinion and of strengthening international machinery by effective cooperation

As in other instances where Great Britain has agreed to incorporate international standards in its legislation, it is possible to claim that our national standard is in advance of the international An Englishman's home is his castle, but in English town life the opinion of the neighbours has always been strong enough to stimulate the law to suppress nuisances It was at all material times a common law offence in this country to keep a brothel, because (in Sir Edward Coke's phrase) such conduct draws together the debauched and dissolute and corrupts public morals by the open profession of lewdness In 1650, during the austere times of the Commonwealth, an Act was passed " for suppression of the deadly sins of incest adultery, and fornication," under which the keeper of a common brothel or bawdy house was to be punished at the first offence with public whipping and branding on the forehead with a hot iron, and at the second offence with death. There was never in modern England any official acceptance of the principle of licensing or toleration of brothels by the State The legislation which began with the Contagious Diseases Prevention Act of 1864, "for the better prevention of contagious diseases at certain naval and military stations," afterwards replaced by the Acts of 1866 to 1869, was repealed after a now forgotten controversy in 1886 Public inquiry into allegations of traffic in girls from England to continental brothels led to the passing of the Criminal Law Amendment Act of 1885 which dealt severely with procuration This Act and its successors have killed the traffic from England to the continent, and legislation such as the Children (Employment Abroad) Act of 1913 and the Theatrical Employers Registration Act of 1925 (which penalises employers who abandon their performers and leave them stranded without pay), as well as enactments respecting health and unemployment insurance and pensions, must play some part in preventing women being driven into the ranks of prostitution by mere economic pressure upon themselves and their dependent relatives It is not easy to see how any further legislation can add safeguards in this country, though possibly additional precautions can be taken administratively by vigilance in the matter of passports and by such measures as are being taken to grapple with the international traffic in dangerous drugs The work of the League of Nations will, of course, receive support in civilised communities, though not a little had been achieved before the League came into existence Under the International Agreement at Paris in 1904 the high contracting parties pledged themselves to certain administrative measures, and under the Paris International Convention of 1910 the signatory nations undertook to penalise and prosecute vigorously the procuration of women and girls The Convention of 1921 contains an article binding Governments to adopt such administrative and legislative arrangements in connexion with immigration and emigration as will check traffic in women and children, and in particular to make regulations for the protection of passengers on emigrant ships at the points of departure and arrival and during the journey The recent report of the League of Nations experts mentions some of the legislative provisions made for this purpose , it also indicates the association between commercialised prostitution and the illicit sale of alcohol, traffic in obscene pictures and books, and the practice of sexual perversion Success in suppressing these latter evils depends, of course, upon the firmness and integrity with which a country's laws are administered

SYPHILIS IN PREGNANCY

Dr J R McCord, of Atlanta, has recently published a short account [1] of 300 consecutive pregnancies in negro women whose Wassermann reaction was " four-plus " Counting abortions, stillbirths, and neonatal deaths, some 34 per cent of the pregnancies ended in disaster The figures make it clear once more that antisyphilitic measures during pregnancy are desirable, for among the 99 women who had prenatal treatment the percentage of accidents was halved—and this in spite of the fact that 43 of them attended tration of alkalies does diminish very considerably the incidence of albuminuria and nephritis, and their views should interest those whose province is the treatment of infectious diseases

SIR GEORGE HUMPHRY, ANATOMIST AND TEACHER

THE last issue of the Annals of Medical History contains a vivid sketch, by Sir Humphry Rolleston, of Sir George Murray Humphry, professor of anatomy in the University of Cambridge from 1866 to 1883, and thereafter professor of surgery for 13 further years Humphry has been dead for 30 years, and that is a long time in a busy world for the personal memory of any man to survive, while Humphry's particular section in that world has undergone a revolutionary transformation during the period But his sound work has passed into scientific history, while his personality was so striking that there must be many readers of THE LANCET for whom Sir Humphry Rolleston's words will recall that frail, gaunt man, who with flashing eye and pentrating voice, revealed to them by illustrations, examples, and references—numberless but without a superabundant word—the mysteries of structure, whether in anatomy or its surgical application "Eyes first, fingers next, ears last!" was, however, Humphry's own warning against acting upon verbal instruction to the neglect of first-hand investigation, and his teaching in the wards ever insisted upon due proportion in observation Humphry's pupils were devoted to him, and as, under the influence mainly of himself and Sir George Paget, the Medical School at Cambridge grew large, an increasing number of men went out into professional life whose attitude towards their work was influenced at its outset—probably far more than they were themselves aware—by Humphry's rigid accuracy, his contempt for the superfluous, and his exhaustive industry where essentials were concerned These men will be grateful to Sir Humphry Rolleston for his note on their master

EPIDEMIC JAUNDICE

EPIDEMICS of jaundice have been described since 1745, when Gleghorn recorded its prevalence in Minorca, but until more than a century later Weil published an account of four cases with a definite symptom-complex no clear distinction between catarrhal and epidemic jaundice seems to have been made Weil's patients suffered from pyrexia, jaundice, enlargement of liver and spleen, hæmorrhages, and febrile relapses Not until 1914 was any light thrown upon the ætiology of the condition though earlier observers had reason to suspect pollution of water as a factor In November, 1914, however, two Japanese workers, Inada and Ido, isolated a highly motile spirochæte, some 7 to 14 μ long, from a patient suffering from the Japanese form of Weil's disease, which has since been known as spirochætosis ictero-hæmorrhagica Noguchi in 1917 pointed out that the organism was characterised by exceedingly fine spirals throughout its length and suggested for it the generic name of leptospira It was recognised among German, French, and British soldiers on the Western front, the diagnosis being confirmed by inoculation of the patient's blood into guinea-pigs and the demonstration in the animal tissues of the spirochæte Since the end of the war epidemics and sporadic cases have been reported from many countries One of these epidemics—that occurring in East Lothian in 1923 among coal-miners—has been studied in detail by Dr George Buchanan under a grant from the Medical Research Council his findings, published to-day,[1] are illustrated by beautiful plates and by microphotographs which vary in their quality He discusses the clinical history, pathology, and morbid anatomy of the condition, as exemplified by 22 cases diagnosed on clinical symptoms and the presence of the spirochæte in the urine and confirmed in two instances by transmission of the disease to animals by inoculation of the urine Experimental investigations take up nearly a third of the book, the concluding sections being devoted to the spread of the disease, bacteriological diagnosis, immunity and serology, and prophylaxis The patients were under the care of Prof G Lovell Gulland, who diagnosed the condition, the chief clinical features being sudden onset with headache, body pains gastro-intestinal symptoms, high fever, slight epistaxis, the appearance of jaundice about the fifth day, a fall of temperature at the end of 11 or 12 days, and the finding of the specific spirochæte in the urine Of the 22 cases 5 were fatal As to the spread of infection, wild rats and field-mice were incriminated as carriers of the causal organism On the experimental side a new observation was that of the presence of a relative small-lymphocytosis in experimental animals within the first few days after infection, and the author suggests that this phenomenon might be of value in diagnosis of human cases Dr Buchanan believes that the portal of entry in human cases is more likely to be the abraded skin, or the mucous membrane of the nose, or the eye, from contaminated hands, than the intestinal tract Inquiry into other possible sources of infection revealed leptospiral organisms in fungal slime hanging from the roof of certain coal-mines and in pit and surface water As to diagnosis, blood examination for the spirochæte proved negative in all cases, as did guinea-pig inoculations with suspected blood, but only three cases were examined by these methods within seven days of the onset of the illness Urinary examinations and inoculations were more helpful, but even these were uncertain and appearances under dark-ground illumination atypical, nor did serological methods yield definite results The author holds, however that in cases of jaundice where clinical signs point to the spirochætal form, where granular spirochætes are found in the urine, the diagnosis of spirochætal jaundice is justified A specific antiserum was prepared but too few cases were available to provide evidence as to its efficiency The chief prophylactic measures recommended are improvement of drainage of infected coal-mines and rat extermination since over a third of the rats examined from the Edinburgh district harbour the organism Seeing that the bibliography refers to some 200 papers on the subject of this disease, the preparation of this book can have been no light task Dr Buchanan has provided, as well as notes of his own patient investigations, a useful index to the literature

THE Rockefeller Medical Fellowships for the academic year 1927–28 will shortly be awarded by the Medical Research Council, and applications should be lodged with the Council not later than June 1st These Fellowships are provided from a fund with which the Medical Research Council have been entrusted by the Rockefeller Foundation Fellowships are awarded by the Council, in accordance with the desire of the Foundation, to graduates who have had some training in research work in the primary sciences of medicine or in clinical medicine or surgery, and are likely to profit by a period of work at a university or other chosen centre in the United States before taking up positions for higher teaching or research in the British Isles A Fellowship will have the value of not less than £350 a year for a single Fellow, with extra allowance for a married Fellow, payable monthly in advance Travelling expenses and some other allowances will be made in addition Full particulars and forms of application are obtainable from the Secretary of the Medical Research Council at 15, York-buildings, Adelphi, London, W C 2

NAVAL MEDICAL COMPASSIONATE FUND —At the quarterly meeting of the directors of this Fund, held on April 21st, Surgeon Vice-Admiral Sir Joseph Chambers, Medical Director-General of the Navy, in the chair, the sum of £210 was distributed among the several applicants was “ loss or decay of many teeth,” and for rejection of apprentices, defective vision. Aural disease comes fourth in this list. Twelve officers and 50 airmen passed the short course in hygiene, and five medical airmen passed the long course. Hygiene and sanitation will be included in the new promotion examination for officers. Details are given of improvements being made in barracks, in drainage, and in water-supply. It is noted that since boots of naval pattern have been on issue no case of hallux rigidus has arisen among the apprentices. These boys are measured and weighed twice yearly, and the rate of growth is satisfactory. During the year 1925, 176 casualties were transferred by air in Iraq, compared with 81 in 1924; this form of transport is now used as a routine. The report contains information about the R.A.F. Central Pathological Laboratory at Halton, and the other six hospital laboratories, and there are returns of the dental work done.

WOLF BOYS.

THAT the latest story of a wolf boy should come from Allahabad is neither surprising nor historically irrelevant, for this great Indian city is in the United Provinces of Agra and Oudh, and no other part of the world has been so prolific in the production of these creatures; indeed, in recent times they have appeared nowhere else. To Major-General Sir W. H. Sleeman, K.C.B., resident at the Court of Lucknow, must be accorded the credit of their introduction to the notice of Europe, for it was in 1858 when he published in London his “ Journey through the Kingdom of Oude ” that England first came to know of their existence. In Vol. I. of this work there is contained a number of stories of wolf boys written in a live and natural manner, and reproducing the style and tone of thought of the Hindustanee narrators. General Sleeman proved himself a good listener, and when the penchant of the gallant soldier became known many there were who assisted him not only wisely but too well in his researches, for all observers maintain that your Indian is ever an adaptable and an imaginative being. In a letter to the *Lucknow Witness* of June 19th, 1874, this explanation of the high local incidence of wolf boys in Oudh is confirmed. The writer of the letter, who was employed in the Oudh Frontier Police and served under General (then Colonel) Sleeman, signs himself as “ O. P. A. ” In his letter he states that “ when the Oudh Durbar officials discovered what they considered to be a ‘ shauk ’ (desire) of the resident, they hastened to produce several unfortunate idiots, positively declaring them to be ‘ wolf boys.’ ” There is no doubt, says this writer, that the natives believe in the existence of these wolf-nourished creatures, but, he asks, “ is it not probably a true solution of the mystery which, for so many years previous to the annexation of Oudh, has enveloped the history of these unfortunate creatures, to suppose that they were simply idiots who, straying away from the place of their birth, wandered, driven by hunger from place to place in search of food; their parents or friends, themselves perhaps poverty-stricken, not being over-anxious to search for and bring back to their homes such burdens on their scanty means? ”

As long ago, too, as August 14th, 1873, there appeared in the *Edinburgh Courant* the following intimation: “ A novelty, in the shape of a ‘ wolf boy,’ has just arrived at Lucknow, and has been handed over to Dr. Whishaw to undergo a process of taming in the lunatic asylum. ” On reading this Dr. Ireland, the medical superintendent of Larbert and noted at the time for his wide and skilled knowledge of mental deficiency, wrote to Dr. Whishaw “ begging him to give some information about the truth of this case which, for the first time, seemed to have come under the observation of one of our own profession. ” Dr. Whishaw’s reply was disconcerting. “ The boy is fourteen,” he wrote, “ and an impostor; he was made up to get money under false pretences. I found him out. I believe never in this world has there been an instance of a child being brought up by wolves, and I cannot understand how anybody can believe in such a thing. It is a common fable in all Indo-European languages. The majority of wolf boys are idiots, taken by their parents and left near some distant police station. ” At about the same time Dr. Ireland was preparing his “Inquiry into Some Accounts of Children being Fostered by Wild Beasts,” which appeared in print in July, 1874. In a subsequent publication dated October of the same year, he quotes the letter by “ O. P. A. ” in full, but it is obvious that he received a copy of it only after he had concluded his original “ Inquiry,” and that he publishes the letter in confirmation of his own conclusion that “ the same explanation seems to do for them all, that idiots have occasionally been found straying in the woods, and that people accounted for their wildness and stupidity, their want of speech, and their abnormal sense of taste, by supposing that they had been brought up by or lived in the company of wild beasts. ” To complete the story, on Nov. 7th, 1874, there appeared in the *Academy*, a paper on the same subject, by Prof. Max Muller, but no mention is made therein of these researches. “ The cases put together by Prof. Max Muller,” writes Dr. Ireland, “ are the same as those already mentioned in my article, which had not the good fortune to attract his notice ”; apparently the examination and conclusion of the medical superintendent of Larbert were distasteful to the speculative aspirations of the learned philologist. Nevertheless, the wolf boy of Allahabad appears to afford additional evidence in favour of Dr. Ireland’s contention, for the facts, as published in the *Times* on April 26th last, show that he has many of the characteristics of an epileptic idiot. “ He has,” says the report, “ a prodigious appetite. He is subject to fits. At times he is ferocious. He has also bitten himself. He is said to betray certain instincts even lower than those of his alleged foster parents. He has a scar on the left side of the face and this has had the effect of dragging the eye down to an unnatural expression. ” Nor need this facial scar have been caused by a wolf, as idiot and epileptic children, especially of rustic, ignorant, and careless parents, are liable to many serious injuries, and some of these do result in hideous scars.

THE PREVENTION OF SCARLATINAL NEPHRITIS.

ALTHOUGH scarlet fever is nowadays a comparatively mild disease, with a mortality of less than 1 per cent., its sequelæ cannot be regarded as negligible. The communication by Dr. A. Osman and Dr. H. Carter, reported on p. 971, has focused attention on the incidence of nephritis as a complication of scarlet fever. Since scarlatinal nephritis is not commonly seen, there is a tendency to regard it as practically non-existent, and to take no steps towards its prevention. However, if all cases of scarlet fever at the various fever hospitals were examined, it would be found that albuminuria is present in from 3 to 5 per cent. and nephritis in from 1 to 2 per cent. Osman and Carter noted an incidence of 5.5 per cent. of albuminuria in 336 cases, while in another series of 316 cases nephritis was present in 2.9 per cent. The presence of albuminuria is in itself significant. It implies damage to the renal tissue, and is a warning to the clinician that the more severe complication of nephritis may ensue if measures are not taken to assist the threatened kidneys. Nephritis with red blood cells and casts in the urine is a serious complication, not only from the immediate danger of uræmia, but also from the subacute or chronic inflammatory processes which may persist in the kidneys. The fact that scarlet fever is a mild disease has no bearing on the severity of the nephritis which may arise as a complication; even a general average of 1 per cent. of nephritis and 5 per cent. of albuminuria is not inconsiderable when the total incidence of scarlet fever on the population is considered. The figures of Osman and Carter indicate that the administermination of the radical breast operation to take precautions against possible or probable parasternal invasion of the thorax by burying radium tubes for 24 hours along the line of the internal mammary glands, placing a tube also in contact with the lowest of the supraclavicular glands at the lower and inner angle of the posterior triangle. In my private cases this policy has justified itself by a diminution of 10 per cent in the recurrence rate. I believe that no operation for breast cancer can in future be regarded as adequate which does not take steps to deal with the danger of parasternal invasion.

Lead Treatment is recommended by Blair Bell as a routine supplement to operation, but some years must elapse before a judgment of its value can be formed. The method has some striking successes to its credit, but it is necessarily attended by a certain risk.

Post-operative Treatment.—A post-operative course of X rays, sufficient merely to stimulate the normal tissues while depressing the vitality of any surviving cancer cells, seems to be a reasonable precaution, but on no account should large doses of high voltage X rays be employed. The "old-fashioned" type of X ray treatment appears to give the best results.

Treatment of Recurrences

With the advent of radium, and increased knowledge how to use it, the prospect in many cases of recurrence, formerly untreatable, has become a hopeful one. This applies especially to recurrence in the supraclavicular triangle, which if detected early can now be treated by excision of glands combined with the use of radium, or by buried radium alone. Such cases may have no further recurrence for ten years or longer.

The same thing is true of recurrence in the sternum, a very painful and common, and formerly quite untreatable, mode of recurrence. Buried radium tubes used on the encirclement principle will frequently suppress the sternal trouble.[1] Of course, in such cases the disease has often spread to the intrathoracic glands, and after a period of activity and freedom from pain, lasting perhaps several years, thoracic metastases terminate existence in a quick and merciful way. Much longer periods of freedom and health may, however, be secured. I have at present under my care in hospital a patient who had a sternal recurrence six years ago. This was suppressed by buried radium. The patient would have passed from observation had it not been for the recent development of secondary carcinoma of the cervical vertebræ. The sternal disease has not recurred.

If treated early on these lines sternal recurrences can mostly be held in check for a considerable period, and exceptionally a permanent cure of the disease after the failure of a radical operation may be attainable. Anyhow, relief of pain and the prevention or cure of external ulceration can generally be counted upon.

For cases of widespread dissemination, where operation and radium are both useless, X rays may be tried, but lead treatment appears to provide a more hopeful alternative.

Prognosis in Breast Cancer.

Breast cancer may be fatal in three months or only after 40 years. In the most acute forms, with "inflammatory" manifestations, prognosis is easy. In the more chronic forms it is impossible until near the end. The disease may creep about in the tortuous recesses of the parietal lymphatic plexus for years without even giving rise to a subcutaneous nodule. Ultimately, at some point or other, permeation penetrates the defences of the body cavity, attacks the bones, or reaches the cranial cavity. When once evidence of visceral disease has declared itself it is rare for life to be prolonged for more than a year, and a definite forecast of the future can be given.

QUEEN CHARLOTTE'S HOSPITAL.

AN APPEAL.

THE urgent need for increasing hospital accommodation for midwifery, and for improving the training of doctors and midwives is reflected in the decision which has been come to by the board of management of Queen Charlotte's Hospital to add considerably to the beds of the institution and to develop the training in accordance with the science of to-day. The following appeal has been sent to the press, signed by the members of the honorary staff.

The Appeal

The public has not generally realised that, though there have been considerable increases in hospital accommodation for general medical and surgical diseases, there has been little real increase for many years in the facilities for the care and treatment of women during the critical times of pregnancy, labour, and the lying-in. As a result there has been a lack of cases required for the teaching and practical training of medical students in midwifery, a deficiency which does not exist to anything like the same extent in other parts of the medical curriculum. It would not be difficult to show that this long-standing lack of hospital facilities for the teaching of obstetrics is largely responsible for the present high and undiminishing rate of maternal mortality and morbidity in this country.

The reasons for this lack of hospital accommodation are:—

1. The maternity charities have not pressed large appeals for funds, and have therefore figured less in the public eye than other special and general hospitals.
2. The public, through lack of education on these matters, do not regard the processes of child-bearing as potentially dangerous or as requiring medical attention, except in cases of emergency.
3. The science of obstetrics has been erroneously regarded as a minor branch of medicine whereas it is in fact of equal, if not greater, importance than medicine and surgery, because every doctor must be ready for the emergencies of midwifery, and must be capable of dealing with them single-handed. Hospital facilities for teaching obstetrics have not been considered indispensable, and expansion in this department has not kept pace with that of other departments.

The results of the neglect by the public and the profession of obstetrical practice are :—

1. Inability to provide sufficient in-patient accommodation for the large number of women who require expert assistance in labour, especially those pregnant for the first time.
2. Totally inadequate provision for the diseases of pregnancy. The available beds are all required for women in labour and the lying-in, making it very difficult to admit those needing treatment, rest, and nursing during pregnancy.

The antenatal care of pregnant women has been demonstrated to be one of the most valuable of all forms of preventive medicine. It must be considered as the most important modern development of obstetrics, and one of its chief activities. Failure to provide facilities for antenatal treatment is one of the most conspicuous pieces of evidence that maternity hospitals are not keeping pace with the movement, and experience emphasises more and more strongly the vital need of preventive methods.

3. Almost no provision of beds for puerperal fever. This is still the chief single cause of death in childbirth, and in 1925 accounted for 1110 fatal cases. It has scarcely diminished during the last 50 years. The maternity hospitals and the general hospitals cannot admit cases of puerperal sepsis, a disease which demands above all things efficient treatment and good hospital nursing.

Apart from the Poor-law infirmaries and some M.A.B. hospitals, it is almost impossible to obtain hospital accommodation for a patient suffering from puerperal sepsis anywhere in London. While all other forms of

Modern Technique in Treatment.

CCXXII

THE TREATMENT OF BREAST CANCER

IN spite of the prevailing medical and lay pessimism about the results of operation for cancer, a pessimism which is founded upon out-of-date experience, the outlook in breast cancer is a very hopeful one, always provided that the disease is detected early and dealt with promptly The treatment of breast cancer is a difficult enterprise, not to be entered upon lightly, nor without due study of the pathology of the disease The primary growth is near the surface and is apparently much easier to deal with than, for instance, a cancer of the cervix uteri But whereas the uterus has a simple and well-defined lymphatic drainage, the breast has multiple and complicated connexions with the lymphatic system which make the surgeon's problem difficult The first local spread of the carcinoma through the breast is facilitated by the particularly rich network of intramammary lymphatics It takes place, not by the slow process of infiltration but by the more rapid method of permeation—the growth of plugs of cancer cells along the lymphatic vessels of the breast Some authors, with little pathological knowledge, still speak of permeation as a hypothesis It is necessary to state that its occurrence and frequency have been established beyond doubt or question by repeated observation In correspondence with the high development of the intramammary lymphatic system the breast possesses numerous and free communications with the rest of the lymphatic system As a result the disease is able to pass early and easily to parts beyond the breast Many of the mammary lymphatics run straight back into that part of the fascial lymphatic plexus which lies upon the great pectoral muscle This is the largest single lymphatic plexus in the body, and gives the disease access ultimately to the whole of the parietal tissues, if time be allowed for permeation to spread. Hence the wide dissemination of skin nodules seen in some late cases of breast cancer

Another route of dissemination, and one which has attracted undue attention because it is patent to clinical observation, is the embolic invasion of the axillary glands of the same side leading to their early enlargement It has been shown that if once the axillary glands are attacked the prognosis for the future must be cautious, even after an efficient operation If the axillary glands are still free from disease the chances appear to be four to one that an operation will rid the patient of her disease If the axillary glands have been invaded, the chances of prolonged freedom from recurrence are about one in four This is a most significant fact

It is, however, very rare for recurrence after operation to occur in the axilla itself, even if the axillary glands are in an advanced stage of disease, if the axilla has been properly cleared by a practised surgeon Clearly, therefore, invasion of the axillary glands is not in itself the explanation of the blight which falls upon the patient's prospects when axillary infection occurs Some other serious event has occurred, an event of which axillary gland invasion is the mere accompaniment and index

Parasternal Invasion of the Thorax

This event is an invasion, simultaneous with the axillary gland invasion, of the glands on the mesial side of the breast, those, namely, of the internal mammary chain lying behind the costal cartilages just outside the border of the sternum These glands lie beyond the range of operation and their condition cannot be determined by any clinical method Unsuspected early invasion of these glands, only manifesting itself after a period which is usually about three years, but which may be as long as 14, is now the most frequent cause of failure after a well planned operation for breast cancer The method of meeting this danger will be discussed later The evidence upon which this conclusion is based is a study of the recurrences after a scientifically planned operation Local and axillary recurrences are reduced almost to zero, and more than half the recurrences *are found either as nodules at the inner ends of the* upper intercostal spaces, or show themselves in the supraclavicular triangle, the glands of which are connected with the internal mammary chain

Epigastric Invasion of the Abdomen

The lower and inner margin of the breast reaches to within an inch of the ensiform cartilage, a region in which the body cavity is ill-defended against the insidious attack of permeation At the tip of the ensiform the only layer which intervenes between the permeated fascial lymphatic plexus and the subserous fat is the linea alba, and this layer is penetrated by lymphatic vessels Fortunately, by removing the dangerous portion of the anterior layer of the rectus sheath it is possible to guard against invasion by this route and in recent years abdominal recurrence has become relatively rare

Method of Operation

Two stages are traceable in the evolution of the operation for breast cancer (*a*) the empirical stage in which the surgeon was guided by a clinical study of previous results, (*b*) the rational stage in which he is guided by knowledge of the mode of spread of the disease The final and best product of the first stage was the operation of Halstead The work of Stiles, and subsequent English work on dissemination, has shown radical defects in the original Halstead method, and it may be said that the modern operation for breast cancer is largely a British product Its aim is to remove intact in a sheath of healthy tissue the primary growth, along with the surrounding permeated area of the lymphatic system and the embolically invaded glands For such an operation the name amputation of the breast is a misnomer The operation must be accurately centred on the primary growth and will therefore differ in each case with the situation of the primary growth in the breast Operative details are here out of place, but it must always be remembered that the disease spreads centrifugally and roughly in a circle from its point of origin, and that the primary plane of spread is the fascial lymphatic plexus, not the skin Removal of a maximal area, 10 in or 12 in in diameter, of the deep fascia is perhaps the most important and difficult part of the operation Failure in this respect and unnecessary ablation of skin appear to be the defects of the original Halstead method

Many technical variations are possible in the operation Some operators prefer to dissect the axilla before removing the breast, believing that thus bleeding is minimised Personally I prefer first to define and dissect up, along with the breast, the large circle of deep fascia in which the growing edge of the disease lies After the axillary dissection this circle cannot be defined with such precision

Diathermy in Breast Surgery

I have been much impressed of late with the advantages of the diathermic knife over the scalpel in breast surgery The whole operation except at the apex of the axilla can be performed as rapidly, and with less bleeding and shock, by diathermy The risk of implantation is done away with The peripheral edge of deep fascia does not need actual removal provided only that the diathermy knife passes along its plane so as to destroy the permeated lymphatics This is an important simplification of the operation The wound may be closed after diathermy just as after a cutting operation and healing is usually satisfactory and painless

Routine Prophylactic Use of Radium at the Operation —For the last six years I have made it a rule at the termination of the radical breast operation to take precautions against possible or probable parasternal invasion of the thorax by burying radium tubes for 24 hours along the line of the internal mammary glands, placing a tube also in contact with the lowest of the supraclavicular glands at the lower and inner angle of the posterior triangle. In my private cases this policy has justified itself by a diminution of 10 per cent. in the recurrence rate. I believe that no operation for breast cancer can in future be regarded as adequate which does not take steps to deal with the danger of parasternal invasion.

Lead Treatment is recommended by Blair Bell as a routine supplement to operation, but some years must elapse before a judgment of its value can be formed. The method has some striking successes to its credit, but it is necessarily attended by a certain risk.

Post-operative Treatment.—A post-operative course of X rays, sufficient merely to stimulate the normal tissues while depressing the vitality of any surviving cancer cells, seems to be a reasonable precaution but on no account should large doses of high voltage X rays be employed. The "old-fashioned" type of X ray treatment appears to give the best results.

Treatment of Recurrence.

With the advent of radium and increased knowledge how to use it, the prospect in many cases of recurrence, formerly untreatable, has become a hopeful one. This applies especially to recurrence in the supraclavicular triangle, which if detected early can now be treated by excision of glands combined with the use of radium or by buried radium alone. Such cases may have no further recurrence for ten years or longer.

The same thing is true of recurrence in the sternum, a very painful and common, and formerly quite untreatable, mode of recurrence. Buried radium tubes used on the encirclement principle will frequently suppress the sternal trouble.[1] Of course, in such cases the disease has often spread to the intrathoracic glands, and after a period of activity and freedom from pain, lasting perhaps several years, thoracic metastases terminate existence in a quick and merciful way. Much longer periods of freedom and health may, however, be secured. I have at present under my care in hospital a patient who had a sternal recurrence six years ago. This was suppressed by buried radium. The patient would have passed from observation had it not been for the recent development of secondary carcinoma of the cervical vertebræ. The sternal disease has not recurred

If treated early on these lines sternal recurrences can mostly be held in check for a considerable period, and exceptionally a permanent cure of the disease after the failure of a radical operation may be attainable. Anyhow, relief of pain and the prevention or cure of external ulceration can generally be counted upon.

For cases of widespread dissemination, where operation and radium are both useless, X rays may be tried, but lead treatment appears to provide a more hopeful alternative.

Prognosis in Breast Cancer.

Breast cancer may be fatal in three months or only after 40 years. In the most acute forms, with "inflammatory" manifestations, prognosis is easy. In the more chronic forms it is impossible until near the end. The disease may creep about in the tortuous recesses of the parietal lymphatic plexus for years without even giving rise to a subcutaneous nodule. Ultimately, at some point or other, permeation penetrates the defences of the body cavity, attacks the bones, or reaches the cranial cavity. When once evidence of visceral disease has declared itself it is rare for life to be prolonged for more than a year, and a definite forecast of the future can be given.

QUEEN CHARLOTTE'S HOSPITAL.

AN APPEAL

The urgent need for increasing hospital accommodation for midwifery, and for improving the training of doctors and midwives is reflected in the decision which has been come to by the board of management of Queen Charlotte's Hospital to add considerably to the beds of the institution and to develop the training in accordance with the science of to-day. The following appeal has been sent to the press, signed by the members of the honorary staff.

The Appeal.

The public has not generally realised that, though there have been considerable increases in hospital accommodation for general medical and surgical diseases, there has been little real increase for many years in the facilities for the care and treatment of women during the critical times of pregnancy, labour, and the lying-in. As a result there has been a lack of cases required for the teaching and practical training of medical students in midwifery, a deficiency which does not exist to anything like the same extent in other parts of the medical curriculum. It would not be difficult to show that this long-standing lack of hospital facilities for the teaching of obstetrics is largely responsible for the present high and undiminishing rate of maternal mortality and morbidity in this country.

The reasons for this lack of hospital accommodation are :—

1. The maternity charities have not pressed large appeals for funds, and have therefore figured less in the public eye than other special and general hospitals.
2. The public, through lack of education on these matters, do not regard the processes of child-bearing as potentially dangerous or as requiring medical attention, except in cases of emergency.
3. The science of obstetrics has been erroneously regarded as a minor branch of medicine, whereas it is in fact of equal, if not greater, importance than medicine and surgery, because every doctor must be ready for the emergencies of midwifery, and must be capable of dealing with them single-handed. Hospital facilities for teaching obstetrics have not been considered indispensable, and expansion in this department has not kept pace with that of other departments.

The results of the neglect by the public and the profession of obstetrical practice are :—

1. Inability to provide sufficient in-patient accommodation for the large number of women who require expert assistance in labour, especially those pregnant for the first time.
2. Totally inadequate provision for the diseases of pregnancy. The available beds are all required for women in labour and the lying-in making it very difficult to admit those needing treatment, rest, and nursing during pregnancy.

The antenatal care of pregnant women has been demonstrated to be one of the most valuable of all forms of preventive medicine. It must be considered as the most important modern development of obstetrics, and one of its chief activities. Failure to provide facilities for antenatal treatment is one of the most conspicuous pieces of evidence that maternity hospitals are not keeping pace with the movement, and experience emphasises more and more strongly the vital need of preventive methods.

3. Almost no provision of beds for puerperal fever. This is still the chief single cause of death in childbirth, and in 1925 accounted for 1110 fatal cases. It has scarcely diminished during the last 50 years. The maternity hospitals and the general hospitals cannot admit cases of puerperal sepsis a disease which demands above all things efficient treatment and good hospital nursing.

Apart from the Poor-law infirmaries and some M.A.B. hospitals, it is almost impossible to obtain hospital accommodation for a patient suffering from puerperal sepsis anywhere in London. While all other forms of acute fever, such as the epidemic fevers, can be admitted to special fever hospitals under the care of experts in these diseases, it is remarkable and discreditable *that no existing hospital is available for the* treatment of this, which is one of the most fatal forms of fever Of this disease there were 2396 cases notified in 1925 Perhaps in no other disease is inexpert treatment likely to be fraught with so much disaster

4 *Inadequate facilities for teaching obstetrics to medical students*

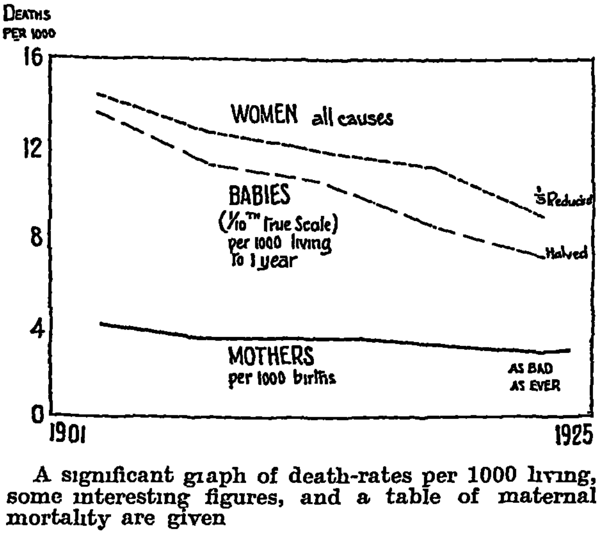
It is not realised by the public how inadequate is the preparation of the student for the practice of midwifery Out of two years clinical training for qualification only five months are allowed for learning the whole of clinical obstetrics and gynæcology—a branch of medicine above all others which he will be called upon to practise single-handed, ready for all its urgent possibilities

5 The continued high rate of maternal mortality and the larger amount of ill-health which may result from childbirth in this country

As an economic factor the latter, largely hidden from the notice of the public, is of great national importance This legacy of ill-health, disability, and *therefore inefficiency of the mother, seriously affects* her capacity for the duties of a housewife and for training a young family of children. The results of this are self-evident More than one-third of all out-patients in a gynæcological hospital are suffering from the results of obstetrical injuries and infections

The committee of management and medical staff of Queen Charlotte's Hospital are impressed by these facts and have decided that there must be considerable expansion in the hospital accommodation, teaching, and research

An important feature of the new building will be the provision of about 25 beds, contained in an isolation flat, for the reception, treatment, and investigation of puerperal sepsis There will also be some beds set aside for the treatment of antenatal conditions



A significant graph of death-rates per 1000 living, some interesting figures, and a table of maternal mortality are given

Table of Maternal Mortality

Year	Death of one mother to—	No of deaths per 1000 births	Year	Death of one mother to—	No of deaths per 1000 births
1897–1906	228 births	4 39	1915	254 births	3 94
1907	261 „	3 83	1916	259 „	3 87

1912	265 „	3 78	1921	270 „	3 70
1913	270 „	3 71	1922	263 „	3 80
1914	253 „	3 95			

To show the Inadequacy of the Present Accommodation

About 4000 women, in- and out-patients, are delivered by Queen Charlotte's Hospital in a year

In 1926 the hospital was *closed 15 times* to further admissions because it was full

In 1926 the hospital was *closed on 46 days* to further admissions because all beds were occupied

Queen Charlotte's Hospital is accordingly appealing for £250,000 to provide buildings which will double the capacity of the hospital, and afford endowment which will enable it to do the work demanded of it unhampered by lack of funds, which cramps the full scientific utility of this institution.

Not only will the hospital itself gain, but it is believed that the wide advertisement and publicity incidental to an appeal and the rebuilding of the oldest and best known lying-in hospital in London, will be forcible evidence of a forward policy in the world of obstetrics, and that it will have its repercussion on the maternity policy of the whole country.

DROITWICH SPA

EXTENSION OF THE BRINE BATHS

ON April 29th Mr Neville Chamberlain, M P, in the presence of a large company of medical men and others interested in spa treatment, opened an extension to the St Andrew's brine baths at Droitwich The extension consists of a block of 17 first-class reclining bathrooms with dressing-rooms adjoining, some additional second-class reclining bathrooms, and further accommodation for aeration baths The new building is so arranged that invalids can be *wheeled directly into the corridors* of the bathrooms, while those who come on foot have no steps to climb

The ceremony was preceded by an agreeable luncheon in the grounds of the Worcestershire Brine Baths Hotel at which the Mayor of Droitwich was supported by the three trustees of the Corbett Estate, who control the bathing establishment—Viscount Cobham, Mr J W Willis Bund, C B E , and Mr Chamberlain himself There were also present Sir William Willcox, Dr Matthew Ray, Dr Fortescue Fox, Dr Percy Roden, ex-mayor, Dr F H Foulds, Dr Malcolm Campbell, Dr John Wilkinson, Dr F I Dawson, Dr C F Curtis, Dr T Stephenson, editor of the *Prescriber*, a number of practitioners from neighbouring towns, and a representative of THE LANCET

Prayers were said by the Rev E H Longland, Mr. Chamberlain declared the building open, and the company adjourned to a reception in the Salters' Hall, where Mr Chamberlain gave an address, not—he was careful to explain—as Minister of Health, but as junior Corbett Trustee The brine baths of Droitwich were, he said, *a great national possession*, known to the Romans, mentioned in Domesday Book, the spring of brine, 200 ft below the surface of the ground, was inexhaustible in quantity, and the strongest in the world Droitwich was protected from winds by the surrounding hills and the climate was bracing and not too cold At St Andrew's baths which were built on modern lines, full use was made of the properties of the brine—stimulating, anodyne, and so buoyant as to give complete and even support to the limbs, whose mobility could thus be restored It was well worth while, said he, to get an attack of rheumatism or lumbago in order to experience the comfort of a bathe in these waters

The amount of invalidity produced by rheumatism was, Mr Chamberlain continued, causing concern to the approved societies Droitwich already catered to some extent for the less well-to-do classes There were 40 beds at St John's Hospital with 450 patients a year, half of them insured persons, supported by friendly societies. In the convalescent home at Highfield 75 beds were provided by working people, through the Birmingham Hospital Saturday Fund without assistance from outside source The local guardians also arranged to take rheumatic patients from other Poor-law unions Under the will of the late Mr Thomas Corbett the whole of the estate would ultimately go in charity The present extension increased the first-class accommodation, but there was, if he might make a suggestion, one thing lacking There was hardly any medical literature about Droitwich methods of treatment The better the article the more it paid to advertise it and an unkind world might not believe that anything at all was being done

Dr Roden told the story of the first use of the brine as a therapeutic measure during the cholera epidemic of a century ago, and the gradual elaboration in the use of the baths, which were now nearly perfect

Sir William Willcox said there was no water in the world with the same properties The brine was 40 per cent more dense than the water of the Dead Sea and was highly radio-active The rheumatic diseases accounted for one-sixth of the whole invalidity of workers and he would like to see the accommodation at Droitwich extended ten-fold The best advertisement for the place was, he thought, the persuasive influence of the cured patient

Dr Ray also returned thanks on behalf of the medical guests

AUSTRALASIAN MEDICAL CONGRESS

(From our own Correspondent)

The Second Session of the Australasian Medical Congress was held at Dunedin, New Zealand, from Feb 3rd to 10th Dr L E Barnett (Dunedin) presided, and the other principal officers were Dr W P Gowland (hon general secretary), Dr A M. Drennan (hon associate secretary), and Dr D W Carmalt-Jones (hon treasurer) There were 425 members present, including 175 Australians and 30 medical women Dr Cooper Pattin was the guest of the Congress, representing the British Medical Association

The first suggestion of a congress of medical men throughout Australia and New Zealand was made in 1886 by Dr Poulton of Adelaide, and an Intercolonial Medical Congress was held in Adelaide in the following year, to commemorate the Jubilee of Queen Victoria The first to be held in New Zealand was at Dunedin in 1896, and the Congress met again in New Zealand in 1914, at Auckland The last of the Intercolonial Congresses was held in Brisbane in 1920, when it was decided to establish the present series under the auspices of the B M.A The first Australasian Medical Congress (B M A) was held in Melbourne in 1923 with Mr (now Sir George) Syme in the chair Great encouragement was then given to New Zealanders to attend, and hopes were expressed that New Zealand would not break away from the Australian States After this the invitation to Dunedin in 1927 was readily accepted.

Inaugural and Scientific Meetings

The inaugural meeting was held on Feb 3rd, and was opened by the Hon W Downie Stewart (Acting Prime Minister), in the unavoidable absence of both the Governor-General and of the Premier, Mr Coates The Hon J. A Young (Minister of Health) welcomed the visitors, and Sir George Syme, the outgoing President, inducted Dr Barnett, who then delivered his presidential address His main topic was that of medical ideals and lay criticism; he welcomed the criticism, but warmly defended the education, discipline, ethical outlook, and practice of the profession He emphasised the attention paid to preventive medicine in the work of the Congress, and outlined the programme He concluded with some remarks upon the challenged ethics of members of hospital staffs, and of prospective changes in hospital accommodation and administration in New Zealand. The entire proceedings were concluded within an hour, and after the inaugural meeting the President and Mrs Barnett held a reception in the adjoining Art Gallery

The scientific meetings were held on Feb 4th, 7th, 8th, and 9th in the Medical School This consists of two buildings, one built in 1916 for the departments of pathology and bacteriology, and one completed just in time for the Congress The latter building is for the departments of anatomy and physiology which were formerly housed at the University of Otago The whole Medical School is now situated immediately opposite the Public Hospital, where the clinical instruction of students is carried out The two buildings turned out to be admirably suited for the purpose of the Congress A general Congress Museum and a special Public Health Museum were both on exhibition, and clinical demonstrations and surgical operations took place in the hospital daily before the sectional meetings began

A general plan was adopted for the scientific work Of the four full days of session one was to be devoted to a subject of New Zealand interest, goitre; one to a subject of Australasian interest, hydatid disease, one to a subject of general interest, diet and the alimentary tract, whilst the remaining day was reserved for presentation of new work Each section was asked to discuss these topics, in so far as they might be appropriate, before proceeding to other work

There were 12 sections—namely, those of medicine, surgery, obstetrics and gynæcology; pathology and bacteriology, preventive medicine and tropical hygiene, ophthalmology, otology, rhinology, and laryngology, neurology and psychiatry, pædiatrics; naval and military subjects, orthopædics, and radiology and medical electricity Combined meetings were frequently held

Visits and Social Functions

For sections interested, visits were arranged to the local Mental Hospital at Seacliff and to the Karitane Hospital for Infants, the Naval and Military Section conducted a staff-ride and tactical exercise A bureau was established by the Government Tourist Department, and visitors were enabled to arrange tours to the various places of interest throughout New Zealand The general office arrangements were excellent, much of the clerical work being carried out by students St Margaret's, the Ladies' College, and Studholme House, the residential quarters of the Home Science School, were made available for the accommodation of visitors Throughout the Congress the weather was excellent, which is unusual during a consecutive week in Dunedin, no less than four large garden parties were given without any of them being marred by rain The City Council entertained a party at Waipori Falls, some 30 miles from Dunedin, where the municipal power-house is situated On the Sunday visits were arranged to Waitati and Warrington, small settlements on the coast some 20 miles to the North, where many of the Dunedin doctors have country cottages

There was no congress dinner, but an official dinner was held at the Dunedin Club The President was in the chair, and proposed the toast of the King The Hon W Downie Stewart proposed the British Medical Association, and Dr Cooper Pattin (England), Dr Antill Pockley (Australia), and Dr Stanley Batchelor (President N Z Branch) replied The Mayor of Dunedin, Mr. H L Tapley, proposed the

Health Services, and the Hon J A. Young (Minister of Health, N Z) Sir George Syme (Melbourne), and Dr Peter Buck (Director of Maori Hygiene) replied Dr J S Elliott (Wellington N Z) proposed the Visitors, and Dr George Piness (U S A) and Dr L A. Kenny (Melbourne) replied Sir Charles Statham (*Speaker of the House of Representatives) proposed* the Australasian Medical Congress and the President replied

Six sectional dinners were arranged at the three principal clubs, and there was also a medical women's dinner A dramatic entertainment was given, and a large amount of private hospitality was shown The social part of the programme concluded with a most enjoyable party given by the President of the Congress and the President and members of the N Z Branch of the B M A at the Savoy Restaurant There was provision for dancing and for bridge, a roof garden was set up to display New Zealand scenes and vegetation, and a performance was given by a troupe of Maori singers and dancers in native costume.

Maori Navigation

During the week the popular lecture generally provided was delivered by Dr Peter Buck (Te Rangi Hiroa), the Director of Maori Hygiene, on the Coming of the Maori He described the remarkable maritime achievements of the Polynesian race, which operated, not like the Phœnicians along the Mediterranean Coast, nor the Scandinavians about the Baltic Peninsula, but among the widely scattered islands of the Pacific archipelagoes in an ocean area which measures perhaps 5000 by 7000 miles Moreover, these feats of seamanship, which include the voyage from Hawaii to New Zealand, across some 60 degrees of latitude, were performed in the Stone Age, for the Polynesians had no metals, they sailed in dug-out canoes, rendered seaworthy by the device of the double canoe which they developed from their original device of the out-rigger The traditional accounts of their great voyages conducted with immense courage and assisted by only the most primitive methods of finding their position are among the greatest romances of the sea

The College of Surgeons of Australasia

During the Congress two important events took place—the inauguration of the College of Surgeons of Australasia, and the establishment of a New Zealand Obstetrical Society

The first meeting of the Founders of the new College was held on Feb 5th, when 18 out of 40 Foundation members were present Sir George Syme presided and described how the idea of the College originated It was first suggested in a letter from Dr Barnett, this year's President of the Medical Congress, to the Surgical Section at the Intercolonial Congress in Brisbane in 1920 , this led to certain activities among surgeons, but the foundation of a college was declined In 1924 Dr Mayo and others from the American College of Surgeons visited Australia and New Zealand, and several surgeons from those Dominions were shortly afterwards admitted to the Fellowship of the American College The opinion developed among these gentlemen that the principles avowed by this College should be universal, and Sir George Syme, Mr Hamilton Russell, and Dr H B Devine undertook a canvass in Australia In 1926 a provisional constitution for a College of Surgeons of Australasia was drawn up, 10 Foundation members were selected, and a provisional committee appointed—not without some adverse criticism A Council of ten was elected, which had met in Dunedin on the previous day, and appointed as officers President, Sir George Syme , Vice-Presidents, Sir A McCormick and Dr L E Barnett. Hon Sec and Treasurer, Dr A L Kenny , and as Director-General, Sir George Syme. By-laws and conditions of membership were drawn up, which include scrutiny of a candidate's education. house appointments, assistantships, teaching posts, hospital appointments, specialties, with the period of his practice, the percentage of professional time devoted to surgery or its branches, and membership of medical societies and contributions to literature A pledge is to be taken by the candidate and evidence must be produced of his surgical judgment and skill and of a high ethical standard These data will be *forwarded to the Credentials* Committee of the candidate's State, which will recommend accordingly

New Zealand Obstetrical Society

This body has come into existence largely through the activities of Dr Doris Gordon, of Stratford It was inaugurated during the Congress, Dr William Irving, of Christchurch, was elected President, and the offices of hon. secretary and treasurer were undertaken by Dr W P Gordon and Dr Doris Gordon Each division of the N Z Branch of the B M A is represented on the Executive Committee, and it is anticipated that there will be 200 members The objects of the society are to raise the standard of obstetrical work and to collect statistics Forms for registration and ultimate collection have already been issued

THE COMMON COLD IN THE UNITED STATES.

It is a standing gibe against the medical profession that they cannot cure a common cold, that curse of our winter months, and it is true that this trivial disability has received little attention from investigators in spite of the amount of misery and off-time for which it is responsible The United States Public Health Service has recently undertaken an epidemiological study of minor respiratory diseases, and its second progress report[1] is based on the data provided by families of University lecturers and of medical officers in the services and public health service The records cover a period of 12 consecutive months, and are classified so as to establish a statistical definition for each diagnostic class and to ascertain for each the incidence-rate and the characteristics of its age, sex, and seasonal distribution The classification was chosen with a view to its use by laymen, and consisted of six groups cold in the nose or head, bronchitis with cough, influenza, sore-throat, tonsillitis or pharyngitis, hay-fever, and pneumonia It is obvious that such an arbitrary grouping leaves much room for redundancy and confusion, even when the symptoms are also given by the reporter. The writers doubt, however, whether any simple classification would have eliminated the difficulties altogether , they give a detailed diagnostic classification, showing all the combinations under which cases were reported, and a table of 13 symptoms, every one of which occurred in each of the five " minor " groups The symptoms thus selected are inflammation of the eyes, running nose, obstruction of nostrils, cough, expectoration, tightness of chest, sore-throat, sudden onset, chill fever, aching in body or limbs, headache, and constipation Those which indicate general constitutional disturbance are, as would be expected, least common in colds, more common in bronchitis, and still more common in cases of sore-throat No doubt the inclusion of some cases of acute follicular tonsillitis accounts for the apparently high frequency of chill and fever in the last-named group

Influenza

The influenza or " grippe " group is interesting as giving an indication of what symptoms are generally held by the physicians of America to constitute a diagnostic basis for this versatile condition It must be remembered that the majority of the reporters were medical practitioners dealing with cases under continuous observation in their own households The tables show that influenza is characterised by a more widespread inflammation of the respiratory tract and a higher frequency of constitutional symptoms. Running and obstruction of the nose, cough and tightness of the chest, and sore-throat naturally occur in a higher percentage in the three groups of cold, bronchitis, and sore-throat respectively, but all the other symptoms were recorded more frequently under the diagnosis of influenza than elsewhere. The authors conclude that as a group the cases classed as "influenza" differ quite definitely and objectively from those classed under the other heads. They compare their own figures with those from the influenza outbreak on Kelly Island,[2] which indicate that the "influenza" cases of this inquiry were more nearly related symptomatically to epidemic influenza than to common colds.

[1] Public Health Reports of the U S Public Health Service Jan 14th, 1927

Attack-rate and Sex Incidence

Studying separately the 775 families (2498 individuals) for whom records are available for the whole year, it is found that the incidence-rate for respiratory disease, apart from hay-fever, is just over 2000 per 1000. For 1500 per 1000 of this "colds" are responsible, while influenzal pneumonia and pneumonia only occur in 4·8 cases per 1000. This incidence-rate in a specially selected group of white people, living under good hygienic conditions in cities, cannot be taken to represent the general incidence throughout the country.

When the sexes are separately considered it is seen that men have rather more respiratory infections than women, except in the sore-throat and hay-fever groups. Women are particularly lucky in respect of influenza and bronchitis, but suffer rather more from hay-fever. The incidence is highest in children under 4 and lowest over 55, declining steadily from its high level in the 25–35 age-group. Adolescents between 15 and 25 suffer least of all the young people. It is interesting to find that each clinical group shows a distinctive age distribution. The incidence of colds diminishes with advancing age, while "sore-throat" shows two peaks, one in childhood and one in middle life. The peak of bronchitis morbidity falls between 5 and 10, and its incidence shows the increase again in old age that would be expected from the mortality statistics.

Seasonal Incidence

For all ages the highest incidence (153·3 per 1000) was recorded for the latter half of January, after which all the conditions gradually declined until the end of November with an intermediate peak in July and early August and another during September. Similar curves were shown in the reports from college students published in the first pamphlet of this series, although their absolute incidence-rate was much higher than among the doctors' families. Both groups came from all parts of the country. No surprise will be felt at the time of highest incidence, but the autumn peak and subsequent decline in early winter is less generally recognised, and longer observations than these will be necessary before the events of 1924 can be established as usual. The hay-fever cases accounted, of course, for the midsummer peak, and the other groups when separately analysed showed peaks corresponding with those of the total curve. Nevertheless, the influenza cases had a distribution quite distinct from that of the colds, the maximum (11 per 1000) being in November and early December, whereas colds maintained a fairly even level (between 5 and 7 per 1000) from September to March. Bronchitis and sore-throat were more irregularly distributed than the others, and there was a striking parallelism between bronchitis and influenza throughout the year.

It would be interesting to have similar figures from this country for comparison. It seems that we cannot blame our peculiar climate for our respiratory distresses, since figures from all over the United States show an incidence in which Northern State runs roughly parallel with Southern, and all are comparable with our own experience here.

---

[2] Public Health Reports, July 22nd, 1922.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

ANNUAL CONGRESS

THE Annual Congress of the Society took place on April 28th, 29th, and 30th, in the hall of the Medical Institution, Liverpool, Sir JOHN HERBERT PARSONS, F.R.S., the President, in the chair. On the first morning of the Congress the members of the Society were officially welcomed to the city by the Lord Mayor of Liverpool, Sir F. C. BOWRING, who also entertained them to luncheon on the same day.

Mr. E. TREACHER COLLINS read a paper on

Metaplasia of the Tissues of the Eyeball.

Metaplasia he defined as the production of specialised tissues from cells which normally produced tissue of other orders, owing to an alteration in environment, and not necessarily, or even primarily, to altered function. He divided the metaplasias met with in ocular tissues into embryological, pathological, neoplastic, and biological. As examples of the embryological, he cited the *formation of a new* lens from the termination of the secondary optic vesicle in larval newts, after destruction or displacement of the normal lens; the production of a lens from an ectoderm which did not normally produce it when either the optic vesicle or the skin overlying it was transplanted in embryo frogs, and in man the substitution of skin for conjunctiva when the eyelids in their development failed to close over the eye. Further examples were the formation, as a congenital abnormality, of bone in the subepithelial tissue of the conjunctiva, the formation of cartilage in place of fibrous tissue in the human sclerotic, and the substitution of retinal tissue for neuroglia in the optic nerve. As examples of pathological metaplasia, Mr. Collins mentioned the formation of bone in the choroid, the substitution of fibrous tissue for the endothelium lining Descemet's membrane, the substitution of stratified horny epithelium for secreting epithelium in cases of xerosis of the conjunctiva, the substitution of yellow elastic tissue for white fibrous tissue in pinguiculæ of the ocular conjunctiva, the substitution of vascular areolar tissue for Bowman's membrane and the anterior layers of the substantia propria of the cornea in cases of pterygium, and the formation of fibrous tissue from epithelial cells lining the lens capsule. In connexion with neoplastic metaplasia, he referred to the formation of spindle-shaped cells in growths primarily endothelial in character, and to the various forms of tissue of mesoblastic origin met with in connexion with tumours of the lacrymal gland and orbit. Under the heading of biological metaplasia he included differences in the constitution of the sclerotic in different species of animals, in some it was composed entirely of fibrous tissue, and in others it contained plates of cartilage or bone. In the choroid the subcapillary fibrillar net in certain animals was, he said, composed of a thin layer of fibres and branching cells, and in others of laminated cellular or laminated fibrous tissue, constituting the tapetum lucidum. The muscular tissue of the iris was composed in some animals of unstriated muscle fibres, in others of striated.

The PRESIDENT said he would not regard pterygium as a metaplasia in the narrow sense in which pathologists generally used that term.

Mr. R. AFFLECK GREEVES read a paper on

Operation for Partial Contraction of Socket.

The essential part of the operation, he said, consisted in the removal of fat and fibrous tissue. Where this was not done, he had not found that suturing had a permanent effect. He did not take away any conjunctiva. Any hæmorrhage which occurred was not difficult to control, nor did he find that the sutures cut out afterwards.

Health Services, and the Hon. J A Young (Minister of Health, N Z), Sir George Syme (Melbourne), and Dr Peter Buck (Director of Maori Hygiene) replied Dr J S Elliott (Wellington N Z) proposed the Visitors, and Dr George Piness (U S A) and Dr L A Kenny (Melbourne) replied Sir Charles Statham (Speaker of the House of Representatives) proposed the Australasian Medical Congress, and the President replied

Six sectional dinners were arranged at the three principal clubs, and there was also a medical women's dinner A dramatic entertainment was given, and a large amount of private hospitality was shown The social part of the programme concluded with a most enjoyable party given by the President of the Congress and the President and members of the N Z Branch of the B M A at the Savoy Restaurant There was provision for dancing and for bridge, a roof garden was set up to display New Zealand scenes and vegetation, and a performance was given by a troupe of Maori singers and dancers in native costume

Maori Navigation

During the week the popular lecture generally provided was delivered by Dr Peter Buck (Te Rangi Hiroa), the Director of Maori Hygiene, on the Coming of the Maori He described the remarkable maritime achievements of the Polynesian race, which operated, not like the Phœnicians along the Mediterranean Coast, nor the Scandinavians about the Baltic Peninsula, but among the widely scattered islands of the Pacific archipelagoes, in an ocean area which measures perhaps 5000 by 7000 miles Moreover, these feats of seamanship which include the voyage from Hawaii to New Zealand, across some 60 degrees of latitude, were performed in the Stone Age, for the Polynesians had no metals, they sailed in dug-out canoes, rendered seaworthy by the device of the double canoe which they developed from their original device of the out-rigger The traditional accounts of their great voyages conducted with immense courage and assisted by only the most primitive methods of finding their position are among the greatest romances of the sea

SCOTLAND

(From our own Correspondent)

Permanent Care of Feeble-minded

The Royal Institution at Larbert has launched an appeal for £70,000 to enable them to develop, to its full powers, the estate acquired for the purpose of colony-care of the feeble-minded Sir John Gilmour, Secretary of State for Scotland, opened the meeting held by the Lord Provost in the Glasgow City Chambers, and gave a direct and stirring exposition of the general problem and of the special work of the institution He lent the full weight of his official and personal views to the new development of "permanent care," explaining that this does not mean obligatory confinement, but simply the making of accommodation available for life-care in cases where the patient's guardians seek it He said that his grandfather had supported the institution from its beginning over 60 years ago, that his father had continued that support, and that he himself had done the same and meant to go on doing it, so convinced was he of the need for this type of accommodation and of the value of the particular scheme As Sir John Gilmour is controlling Minister of the General Board of Control, this expression of attitude has exceptional importance A comprehensive and elegant speech from Sir Donald MacAlister, the Principal of the University, further brought out the points of the appeal from both the medical and the public points of view

A short time ago the Scottish Council of Women Citizens Associations handed to the Larbert Institution the handsome sum of £12,000 on condition that the institution would develop a colony for permanent care The agitation that ended in this sum of money began over four years ago, and the Women Citizens succeeded in rousing the authorities of Scotland to a consciousness of their duty in this field The present appeal will reap where the Women Citizens have sown, and there is little doubt that the £70,000 will ultimately be secured

Radiological Facilities at Edinburgh Royal Infirmary

At the monthly meeting of the Edinburgh Insurance Committee a letter was read from the clerk and treasurer of the infirmary stating that it had been decided to extend facilities for the examination or treatment by the radiologist of patients who are unable to pay the usual private fees, and for treatment by apparatus and appliances not otherwise available in the city or district—on the footing that the patients would give an appropriate donation to help to defray the expense incurred The committee expressed their great appreciation of the facilities thus placed at the disposal of the community by the infirmary authorities, and each practitioner on the committee's list will be communicated with This is an excellent example of how such expensively public-provided installations can be used to extend the powers of the general practitioner

Change of Doctor

The Coatbridge Insurance Committee some time ago passed the following resolution "That the Committee is of opinion that a material cause of the increase on sickness benefit claims is due to the present system, which allows change of doctor at any time, and that the former system should be reverted to and change of doctor only be permitted half-yearly" The Edinburgh Committee discussed the point at great length once more and, by a large majority, agreed to recommend that the present system be retained Probably Coatbridge means the *fear* of change of doctor rather than the actual change The known administrative facts seem to point that way

Bootle	12,071	10,852	3,728	12,690	26 0
Bedfordshire	—†	—†	5,182	1,451	18 85

* Excluding uncleanliness and dental defects † Not given.

Gillingham

Dr W A Muir gives a concise statistical summary of the medical work during 1926, of which the net cost to the ratepayers was approximately ¾*d* in the £ "The washing and sanitary accommodation inside some of the schools," he writes, "does not reach a high standard of cleanliness, quite apart from the question of some of it being out of date from a hygienic standpoint The influence of precept on the young child is very little, that of example is immeasurable" Uncleanliness of this sort should not be tolerated by any education authority as it cuts at the roots of the whole medical work, in Gillingham it is associated with a lack of facilities for treating exceptional children in open-air and special classes, and an absence of orthopædic arrangements found in many comparable areas The high percentage of parents (90 per cent with entrants) attending the medical examination shows the interest taken by parents in the welfare of their children The medical work is of a satisfactory nature all round, defects of the nose, throat, ears, and eyes are well treated. Here, as elsewhere, there is a disinclination to take full advantage of the dental treatment offered; and only 33 per cent of those requiring dental treatment obtained it Measles and mumps epidemics during 1926 entailed much extra home visiting and laid an additional strain on the nurses, of whom there are only two This may account for the rise in the numbers of children found verminous from 16 3 in 1925 to 17 3 per cent in 1926

Bootle

Dr F T H Wood opens his nineteenth annual report with a satisfactory answer to the question as to whether the medical service has evidence of any substantial improvement in the physique and hygiene of the school population Personal cleanliness and freedom from parasites show a remarkable change, largely due to the activities of the school medical service Physique, as estimated by measurement of height and weight, shows an advance in places, while there is an obvious diminution in the severe degree of rickety deformities formerly seen Defects of the teeth, eyes, nose, and throat call for more attention to the health of the pre-school child, only by sustained effort from the earliest ages can the maximum improvement in national health be maintained. Referring to Dr H C C Mann's report to the Medical Research Council on the feeding of school-boys, Dr. Wood believes it would be to the advantage of the public health of the country if—concurrently with the improvement now being aimed at in the cleanliness and safety of the milk-supply—a large increase in its consumption above the half-pint daily average could be obtained In view of the continued unfavourable economic conditions the increase in ill-nourished children from 6 1 per cent in 1925 to 7 6 per cent in 1926 is not surprising Using the "forced whisper" test in the intermediate and leaving groups some defect in hearing was recorded in 12 5 per cent boys and 10 0 per cent girls in the great majority the defect being of moderate degree The presence of these minor degrees

The paper was discussed by Mr **THOMSON HENDERSON** (who stated that he had performed a similar operation ten years ago), Sir **ARNOLD LAWSON**, Mr **GEORGE MAXTED**, Mr **J GRAY CLEGG**, and the **PRESIDENT**

Dr **GEORGE YOUNG** (Colchester) read a paper entitled Practical Keratometry, which was discussed by several members

Dr **P STIBBE** demonstrated specimens illustrating the comparative anatomy of the nictitating membrane

Thursday afternoon was devoted to a discussion on

Nystagmus (other than Miners')

Mr **BERNARD CHAVASSE** said that there were several pathways along which the subject could be approached Nystagmus could be regarded either as a movement, a disease, a symptom, an adaptation, a habit, or as a problem in neurology These views represented a natural series in a progressive order of research, culminating in a study of the nervous mechanisms as constituting the heart of the problem

True nystagmus—i e, that which was present when the eyes were looking straight-forwards—might increase in certain directions of the gaze, and so assume the primary characteristic of a pseudo-nystagmus He suggested that the terms "with field central," "with field peripheral," "with field upwards," &c, should be used to replace the old distinction between nystagmus and pseudo-nystagmus If the nystagmus was jerking, but with a widespread field, and was uninfluenced by occlusion, a more widespread affection was probable If the movements were dissociated in the two eyes, it was likely that a comparatively peripheral lesion was present If it was associated, the physician would suspect a lesion of higher or more remote centres, influencing the intact neuromuscular end-organ as a whole Any bilaterally acting semi-superable obstacle to acute vision, whether actually existing or by the induction of a habit, might produce a smooth bilateral nystagmus, with its widespread or universal field Mr Chavasse discussed at some length, with the aid of diagrams, nystagmus as a neurological phenomenon

Dr **HUGH JONES** exhibited a model which had been devised for demonstrating the positions of the semicircular canals in relation to other structures in various postures, and the movements of the otoliths and the consequent pressure exerted by them He demonstrated the absence of nystagmus in a man who, following double acute labyrinthitis which he refused to have treated, was rotated rapidly ten times in the revolving chair and then suddenly stopped, both labyrinths were entirely inactive In all vestibular tests, said Dr Jones, the absence of reaction was at least as important as the presence of reaction

Dr **GORDON HOLMES** dealt with the neurological aspect He said the field of vision was dependent on vestibular components which compensated movements of the head and body, on visual components which compensated movements of the eyes *plus* voluntary components which adjusted the eyes, and on stimuli of sight in the field of vision All these must be taken into account in any discussion on nystagmus The neurologist was chiefly interested in the central mechanisms normally concerned in the adjustment of the eyes, and to him the vestibular component was the important one He proceeded to detail the parts of the central nervous system from which nystagmus might arise It depended on lesions of those paths and centres which were limited to the hind-brain and intimately connected with the vestibular apparatus These he dealt with in detail He dissented wholly from the view put forward in a recent monograph that nystagmus could be regarded as a tremor of the eyes, it was, he said, a definite coordinative act It could occur even when the muscles were palsied, or indeed completely paralysed He had described a case of complete external rectus palsy on the right side, associated with a cerebellar lesion, in which nystagmus was regular and symmetrical in the two eyes This must be, at least in part, because there was a reciprocal innervation of the antagonistic muscles—i e, the movement was largely the result of relaxation of the internal rectus of the right eye Though, usually, nystagmus was designated according to the direction of the rapid phase, the slow phase was the essential feature In many conditions there was a terminal fixation nystagmus—that is there were a few jerks of the eyes when the patient first fixed in any position but that of primary rest It occurred, for instance, in asthenic states, as during convalescence from an acute illness, and in intoxications, especially chronic alcoholic intoxications He thought this was the form of nystagmus occasionally found in alcoholic neuritis, though a definite lesion of the nerve could not be excluded It might also be the result of a defective fixation reflex, such as occurred in amblyopia He asked whether nystagmus ever resulted from a primary lesion of the cortex or of the fore-brain as such He had examined thousands of cases of gunshot wound of this region, and had never seen nystagmus of any form resulting from such wounds unless the brain was also extensively infected He believed that in no condition did nystagmus of the type he had referred to result from a lesion of the cortex, or even from a lesion of any part of the fore-brain

Mr **SYDNEY SCOTT** discussed the subject from the otological point of view, remarking at the outset that 30 years ago Dr Hughlings Jackson had described a case of labyrinthine nystagmus Most otologists had accepted nomenclature concerning nystagmus which was purely conventional, and possibly it might clash with that adopted by ophthalmic surgeons and by neurologists Otologists' observations were made in people with normal vision, and in considering labyrinthine nystagmus he would exclude cases of central nervous disease, disseminated sclerosis, Friedreich's ataxy, and similar conditions It was assumed that nystagmus could be set up in the labyrinth as the result of irritation, and by a caloric stimulus When it was evoked by such stimuli it must be assumed there was no spontaneous nystagmus in the particular person, as the means of producing it were all excessive stimuli When testing for this phenomenon it was important to get the patient to look at a small object held not less than 18 inches from the eyes, the head being kept quite still and the eyes following the moving object as it was brought to the extremity of the binocular fields Nystagmus evoked with the eyes beyond that limit was disregarded in otological clinics as it was present in 60 per cent of normal people when that range was exceeded Sometimes he was asked, in particular cases, whether the nystagmus was the cause of the vertigo, or vice versa The otologist regarded both as due to a common cause, neither was dependent on the other But nystagmus was not associated with vertigo when it was not of labyrinthine origin When using the caloric test it was very important to have the patient's head fixed in a slightly forward position in relation to the trunk Apart from cerebellar disease, there were certain conditions in which labyrinthine disturbance occurred for a short time In acute otitis media a nystagmus was sometimes met with which must be distinguished from that which followed destruction of the labyrinth When the phenomenon was due to otitis media it would disappear when the tympanum was drained, and there was no immediate risk of extension to the labyrinth or to the meninges If there was a negative response to the caloric test, however, the labyrinth should immediately be opened Nystagmus was also present in chronic fistula

(*To be concluded*)

WESTMINSTER OPHTHALMIC HOSPITAL—The annual report of this hospital records the unusual experience of a reduction in the number of patients treated, in-patients having fallen from 919 to 863, and out-patients from 14,905 to 14,010 The committee attribute these reductions to the general strike in May last Casualties, however, increased from 2007 in 1925 to 2285 health. That however, was not the case, and while over £1,000,000 a year was raised by this taxation, the Government were not spending more, he believed, than £200,000 on medical research

On a division the resolution was agreed to by 251 votes to 116

ACCIDENTS IN MINES

On Wednesday, April 27th, Mr George Hirst moved :—

" That this House deplores the heavy loss of life and the large number of non fatal accidents in mines, and regrets the failure of the Government to give effect to repeated pledges that every possible step would be taken without delay, whether by legislation or otherwise to secure the fullest protection to those engaged in this dangerous industry "

He said that one would imagine when motions of this description had been introduced from time to time in that House and when statements had been made bringing the facts before the notice of the Government that the latter would do all in their power to introduce regulations to minimise accidents in mines But nothing had been done so far as they could discover to prevent a recurrence of the serious accidents which had taken place, and were still taking place This was a very important question, and ought to be dealt with very seriously He had made a comparison between the number of accidents which occurred during the time when the men were working seven hours a day and the number of accidents under the eight hours' day, and he found that the latter figures were tremendously larger than the former Working out the averages of fatal accidents during the eight hours' system and the seven hours' system over a number of years they found that the figures showed 260 more deaths per year under the eight hour day than under the seven hour day The Secretary for Mines had stated in answer to a question that there had been 306 deaths, and 1214 persons had been seriously injured through accidents in coal mines, in the first three months of 1926 under the seven hours' rule The corresponding figures for the first three months of 1927 were 324 killed and 1291 seriously injured. The purpose of that debate was to draw the attention of the Mines Department to the fact that something ought to be done to prevent the terrible accidents He made several suggestions in 1925 during a previous debate on this subject as to steps which he thought the Mines Department ought to take The proposal to abolish the Mines Department was absolutely ridiculous He hoped that the Chancellor of the Exchequer and the Government would leave that Department alone. Instead of doing away with it they ought to add to it more people who had direct knowledge of the working of mines so that they might minimise the number of these accidents to a great extent One of the suggestions he had made was that more shafts should be sunk. At the present time mines were being worked where men had to walk from two to three miles from the shaft bottom to the working face The sinking of new shafts would have a tendency to reduce accidents It would improve the ventilation and improve the health of the miners It would also reduce the risk of explosion and also falls from the roof and sides by stopping the accumulation of gas

Mr Grundy, in seconding the motion, said that the Mines Department had all the accumulated expert knowledge in regard to this subject, and the evidence which had been taken at various inquiries into accidents that had occurred from time to time, yet since 1911 there had been no legislation aimed at giving additional safety to the men who worked under these dangerous conditions There were 3000 pits but he wished to ask whether there were sufficient inspectors to inspect them ? What was being done with regard to nystagmus, about which there were startling figures ? A committee of the Medical Research Council reported in 1922–23 that the chief cause of the disease was insufficient illumination, and that the cases severe enough to cause disablement could by degrees be entirely prevented by improving the standard of lighting From 1905 to 1912 there were 1760 cases of nystagmus , in 1913, 4550 , in 1920, 7028 , in 1921, 6717 , in 1922, 9155 , in 1923, 11,142 , in 1924, 10 906 , and in 1925, 11,334 If it was possible by any means, no matter at what cost, these cases of nystagmus ought to be decreased There was only one class of employment that had a greater fatality-rate than mining In 1922 fatalities in mines amounted to 95 , in shipping it was 1 33 In 1923 the figure was 1 06, against 1 14 for shipping , and in 1924 it was 1 05, against 1 39 for shipping The non-fatal accidents in mines in 1922 was 160 056 In shipping they were 18,066 In 1923 non-fatal accidents in mines were 177,011 , in shipping they were 1791 Accidents in mines were eight times as many as in docks, and five times the average of factories, docks, quarries, constructional works and railways taken together

Mr R Hudson moved to leave out from the word " mines " to the end of the motion, and to add instead the words :—

" but recognises that steady progress is being made towards the attainment of safer conditions by means of regulations, research, inquiry, and inspection, as a result of which the safety of mining in the country compares on the whole very favourably with that in other countries "

He said he did not think it was right that party capital should be made out of a subject which affected the lives and happiness of so many of their fellow men engaged in one of the main industries of the country When they read the annual reports of the inspectors of mines they must be impressed with the fact that they harped year after year on one subject—namely, the avoidability of many of these accidents But in spite of that they had the same thing cropping up again and again After looking at the more depressing side of this subject had they no ground for hope ? If they compared the conditions in this country with those abroad were we better off, or could we learn any lessons from foreign countries ? He had looked up in one of the reports the figures of the mean annual death-rate for two periods of ten years—namely, 1903 to 1912 and 1913 to 1922 In Great Britain the percentage was 1 3 in the first period and 1 2 in the second period , in the United States the percentage was 5 1 in the first period and 4 3 in the second period , in Belgium 1 0 and 1 2 ; in the Netherlands 1 8 and 1 7 , and in Germany 2 1 and 2 8. These figures applied to the same period The only country which had a lower death-rate than ours in this respect was France, where it was 1 0 If they examined the British figures they would find that there had been a sensible improvement There were fewer people killed in 1925 than in 1924, and if they took the rate per 100,000 man shifts worked between 1922 and 1925 they would find that it had fallen from 66 3 to 63 9 He agreed that they ought to inquire whether everything possible had been done to minimise accidents, but never during the past ten years had so much been actually done to deal with the really basic problems of industry as they affected the health efficiency and the comfort of the individual worker The Institute of Industrial Psychology, the Medical Research Council, the Industrial Fatigue Research Board, the Safety in Mines Research Board, and other organisations too numerous to mention, were carrying on an intensive campaign An immense amount of information was being gathered from other industries which was applicable to coal mines These investigations had shown the importance of ventilation, and the subject was being intensively studied by a committee of the Institution of Mining Engineers, and when the engineering problems had been solved, they might anticipate a corresponding diminution in the accident-rate The importance to the country as a whole of these discoveries needed no emphasising when they considered the extent to which our shallower seams were being worked out There were some interesting results showing the human factor as the cause of accidents, from which it appeared that in any particular group of men there were certain individuals whose liability to accidents was greater than others If means could be devised of discovering these people at an early age and setting them to jobs involving less danger the accident-rate would decrease, not only in mines but in other dangerous industries as well. It was the daily accidents which they wanted to avoid, even more than the big spectacular accidents which struck public opinion from time to time He had seen it estimated that compensation for accidents imposed a cost of something like 3*d* per ton of coal raised in this country A great deal had been done by way of inculcating " safety first," but there again education was sadly needed, and the need for it was strikingly illustrated in the report of the Inspector for the Northern Division Speaking of 1925 he said that of the deaths caused by explosives 67 per cent were due to clear breaches of the regulations ; 61 of the non-fatal cases were due to the same cause , while 30 per cent of the remainder could have been avoided by the exercise of due caution The seven years' figures were worse still Ninety per cent of the fatal accidents and 80 per cent of the non-fatal accidents were due, he said, to breaches of the Explosives in Coal Mines Orders That was a situation appalling to contemplate In another passage the inspector deplored the lack of any real organised coöperation in safety matters between owners and workmen There was, he said, a tendency on the part of the workers to expect all action for protection to come from the official side. It had been said that no action had been taken by way of legislation to assist in the prevention of accidents, but he thought that the passing of the Mining Industry Act of last year and the increase in the amount of money available for the welfare fund could not fail by increasing the general physique and well-being of the men engaged in the industry to have its results in diminishing the number of accidents

Mr Clarry, in seconding the amendment, said that the work of securing greater safety in mines was being carried on to the best of the ability of those engaged in it There was no section of the community which would not do everything in its power to render the mines safer in working. Science and human ingenuity were hard at work all the time with that end in view of deafness is often overlooked, although they are of considerable moment to educational progress and success in the labour market No school department was closed on account of infectious disease during the year Of the total number of days lost through sickness impetigo was responsible for the largest amount Of the 82 ascertained educable feeble-minded children in the borough 21 attend special classes, 28 are in ordinary elementary classes, and 31 are not attending any school or institution Supervision of this last group is obtained by home visits from the nurses, supplemented by individual re-examination by the school medical officer

Bedfordshire

In this report Dr R T Herdman shows how difficulties can be met by goodwill and efficient organisation For the sake of economy and better education, older children are being taken away from the small village schools to larger ones some distance away. Transport difficulties are real, but are being got over, as is the difficulty of the midday meal which is being provided at the school With good management and by making full use of school gardens, themselves agencies of great educational value, it is found possible to keep the actual cost of the food that has to be bought to 1*s* a week per child These school dinners have other advantages in the training of children, and may help to maintain the higher standard of physique and nutrition shown to exist in the year under review The risk of chill from sitting in wet boots is obviated by the use of slippers, supplied by the parents or made in the school at a small charge for material—another instance of practical education It is suggested that these elder children could be medically examined at their local rural schools, so as to give their parents opportunity of direct speech with the examining doctor, the teachers at the senior schools being notified in writing of any defects discovered There are as yet no special schools in the county maintained by the authority , the obstacles of providing them in such scattered districts are manifest, but it is to be hoped they may be overcome by organisation similar to that which has produced central schools

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED APRIL 23RD, 1927

Notifications —The following cases of infectious disease were notified during the week Small-pox, 358 (last week 348) , scarlet fever, 1202 , diphtheria, 761 ; enteric fever, 47 , pneumonia, 1061 , puerperal fever, 38 , puerperal pyrexia, 98 , cerebro-spinal fever 8 , acute poliomyelitis, 5 , acute polio-encephalitis, 1 , encephalitis lethargica, 30 , continued fever, 1 , dysentery, 8 , ophthalmia neonatorum, 120 No case of cholera, plague, or typhus fever was notified during the week

The cases of small-pox were notified from the counties of Derby 18 (10 of these from the county borough), Durham 149, Kent 1 (Gravesend), Northumberland 17, Nottingham 1, Yorks North Riding 7, West Riding 72, Monmouth 90 (of these 57 from Abersychan and 18 from Blaenavon) The small outbreak at Hendon (Middlesex) is still unnoticed in the official return , there have been 8 cases with 3 deaths reported in the daily press

Deaths —In the aggregate of great towns including London there was no death from small-pox, 1 (0) from enteric fever, 81 (4) from measles, 4 (1) from scarlet fever, 46 (18) from whooping-cough, 27 (7) from diphtheria, 53 (14) from diarrhœa and enteritis under two years, and 82 (17) from influenza The figures in parentheses are those for London itself

The fatal case of small-pox from Sheffield included in the return for March 26th occurred in a prematurely-born infant three weeks old, whose mother had contracted the disease The child weighed only a little over 1 lb at birth and was so weakly that it was deemed inadvisable to vaccinate it Dr F E Wynne, who sends us this information, considers it unlikely that the child would have survived in any case No information is yet available as to the type of small-pox in the three fatal cases reported from Hendon

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

PATENT MEDICINE DUTY

ON Tuesday, April 26th, the House of Commons considered the Budget Resolutions on Report

On the resolution for the continuance of the additional excise duty on patent medicines,

Lieut -Commander **KENWORTHY** said he believed the actual amount produced by the duty was something like £300,000 a year This was a very small part of the total revenue, but it meant a good deal to very poor people who had to buy these patent medicines because they could not afford, in many cases, to get any other kind of doctoring. He did not know whether the patent medicines did them any harm or good , that might be arguable, but the fact was these people took them Well-to-do people who bought these medicines did not feel the tax at all, but poor women and others felt every halfpenny when they were living on a few shillings a week and were beginning to ail in their advancing years It would be a humanitarian act for the House to remove this tax on the sick and ailing He never heard of any doctor who was particularly keen on this tax, though he dare say *some, for purely selfish reasons,* might object to people buying patent medicines instead of consulting a doctor

Mr **HARRIS** said that it must be assumed that these medicines were of some good for health, for if not the Ministry of Health, would, they must assume, interfere and prohibit their use and sale If they were good for curing ills, as they were advertised to be, surely it was a wrong thing to subject them to a duty dating back as far as 1783, which had never been defined or codified or made clear to the public, and which, from the point of view of revenue, or of incidence, or of finance, or of cost of collection, was thoroughly unsound in principle, and quite against the canons of sound finance

Mr R **McNEILL** (Financial Secretary of the Treasury) said that the revenue derived from this duty was pretty considerable They estimated the income from it this year at £1,340,000, which was not to be despised in times like these On that ground alone he would have to ask the House to maintain this duty The reason why the duty was being made permanent was that as a matter of fact since it was doubled in 1915, the working of the duty had shown that this particular commodity could very well bear the tax which, had been put upon it for ten years without in any way decreasing consumption, and at the same time allowing for a very large increase of revenue Most people would agree that if a tax was put too high on any particular commodity of this sort, the tax showed itself in a decrease of revenue In point of fact, since the rate was doubled in 1915 the actual yield from this duty had gone up nearly four times This showed that this was a legitimate source of revenue which it was now proposed to make permanent This tax was originally, and was still in principle a tax on quack medicines No real medicine recommended by a qualified physician and coming under a certain definition and supplied as part of the ordinary British Pharmacopœia came under the duty at all The tax applied to patent medicines which were or purported to be of a proprietary or secret character

Major **CRAWFURD** The right hon gentleman said this was originally meant to be a tax on quack medicines He is surely not going to apply that phrase to all patent medicines The tax may be a good or bad one, but all proprietary medicines are not necessarily quack medicines

Mr **McNEILL** That of course depends on what is your definition of quack, but that was the original intention

Mr **HARDIE** said that poor people who could not afford to go to Harley-street specialists or to get any specialised advice often went without food to buy some positive remedy which they had seen advertised in a newspaper and which they hoped would do good to some member of their family The number of people who could not get specialised medical advice and treatment was increasing, and such people took these patent medicines as the next best thing He urged that the Government should give some guarantee of these medicines

Mr **THURTLE** said that it was the poor who had so little money to spend on medical advice and attention that were most in need of it They lived in very crowded housing conditions, and consumed inferior food He protested against the absence of any representative of the Ministry of Health during a debate which concerned the health of the great mass of the people

Mr **MOSLEY** said that if these patent medicines were bad they should be stopped by law, but if there was any good in them they should not be subject to taxation But he would not object to this tax on possibly indifferent medicines if the Government was returning the proceeds of the taxation for the improvememt of the general science of medicine and the Bill would pass, but she was sorry that the Government were going to oppose it She believed that women had a right to judge whether they ought to work or not

After further discussion,

Mr RONALD MCNEILL (Financial Secretary to the Treasury) said that if this Bill were passed it would effect a far-reaching and important change in the administration not only of the departments of the central government of the State, but all the departments of the innumerable local authorities Whether hon Members thought that the proposed change would be desirable or undesirable they must recognise that it could only be made on the initiative of the Government of the day There had not been the slightest indication in the debate that there was any support for the Bill among the great popularly elected bodies of the country He opposed the Bill first of all in the interests of women themselves The ultimate tendency of such legislation would be to discourage the employment of women, married or unmarried This was not a question which ought to be decided on principle The whole question here was whether or not the Bill would improve or not improve the public service, and, secondly, whether the proposed change would do an injustice to any individuals, either men or women Inefficiency was a relative term A person might be very efficient at one moment and quite inefficient at another That was why he thought there was no real analogy between the public service and other callings, such as medicine and the law It did not make much difference to the solicitor or the doctor or the actress if they happened to be in a state of health at any given moment which compelled them to retire temporarily from their work It might be an inconvenience and a loss, but it did not affect gravely or permanently their efficiency in that particular employment It was a totally different thing in the Civil Service and in the carrying out of the great machinery of government. Obviously women and men alike in the public service must take the ordinary sickness risk. It could not be eliminated, but they tried to get the risk as low as possible by medical examination. What the supporters of this Bill were asking the Government to do was to increase the sickness risk—the risk of discontinuance of service—in the case of women after they were married It was common medical knowledge that in some cases pregnancy inflicted great loss of health and strength and spirits on a woman, sometimes for many months, while others who were differently constituted would go on until within a few days of confinement without apparently suffering any loss of physical vigour These facts added enormously to the sickness risk which the Government would have to take with the consequent immense loss over the whole service of efficiency on which the conduct of the service rested Having regard to all these considerations, he hoped that the House would not be led astray in this matter

Dr LITTLE said that the opposition to the Bill seemed to be largely founded on what he thought were fallacious medical propositions The objection to the employment of women seemed to rest largely on a physiological incident of life among married women But did men suffer from no sexual disability? He thought that anyone comparing the numbers of absentees in any service, both male and female, would find quite as many males suffer from sexual disability, and absences from this cause were an important set-off to the absences of women as a result of disability arising from sex The universities of this country had had this question before them, and had solved it for themselves They had made no distinction whatever between the sexes He submitted that there was no support for what he called the medical argument It had not been urged by any medical authority, and it fell to the ground the moment that it was examined

On a division the Bill was rejected by 84 votes to 63

PROTECTION OF DOGS BILL.

On April 29th **SIR ROBERT GOWER**, in moving the second reading of the Dogs Protection Bill, said that it provided that it should be unlawful to perform any experiment of a nature calculated to give pain or disease to any dog for any purpose whatsoever, either with or without anæsthetics, and that no person or place should be licensed for the purpose of performing any such experiments On three occasions this Bill had secured a second reading in that House, on two occasions without a division, and once with a division when it passed through the Committee subject to an amendment which was suggested by the Government, and when, had it not been for an unfortunate accident, which prevented it securing a third reading, it would undoubtedly have been placed on the Statute Book The Bill was not brought forward with any desire to obstruct or hamper legitimate surgical or medical research The general question of the vivisection of animals did not arise in the consideration of this Bill, which applied to one animal only—namely, the dog Since the Bill was presented to the House a rather keen controversy had been waged in the *Times*, and two eminent medical men, Sir Charles Ballance and Mr Walter Spencer, inserted in that newspaper a manifesto in opposition to this particular Bill In reply to that manifesto a letter appeared from Dr. Fielding-Ould, who, he thought, would be admitted by those connected with the medical profession to be one of the most eminent and distinguished members of that profession After referring to the statement which Sir Charles Ballance and Mr Spencer had made, Dr Fielding-Ould said —

> "We cannot find any justification for the continued use of cats and dogs in research These domestic animals have become, by close association with man, more and more sensitive, and unless vivisectors can give convincing proof of the necessity, then their continued use for experimental purposes amounts to deliberate cruelty, and offends the moral sense of very many thinking people "

He went on to say —

> "The onus of proving the necessity lies with the vivisectors and at present there is no proof whatever, nor does Sir Charles Ballance attempt it "

He also said, and he (Sir R Gower) thought that hon Members who had followed this controversy for years past would agree that such was the fact —

> "It is the reasoned opinion of very many scientific men that dogs and cats may reasonably be exempted from experiment without impeding the progress of scientific research in the least "

The House would observe that in this letter Dr Fielding-Ould laid down a very definite challenge not only to Sir Charles Ballance and Mr Spencer but to the medical profession at large They would imagine that if the case of those who were opposing the Bill were strong they would have accepted the challenge laid down and would have written to the *Times* or to some of their publications providing the proof asked for It was perfectly true that Sir Charles Ballance and Mr Spencer considered it necessary to reply to Dr Fielding-Ould's letter in the *Times*, but in their reply they emphatically disclosed their objection to the Bill They made no attempt at all effectively to rebut the statements of Dr Fielding-Ould, but gave as their chief reason of objection to the Bill the following "The Dogs Protection Bill is the thin end of the wedge, the object being to stop all research by vivisection in this country" Lord Banbury, when introducing a Bill similar to this in the House of Lords, some time ago gave a quotation from a speech made by Sir Lambert Ormsby in April, 1922, as follows —

> "Experiments on dogs might now be discontinued All that can be found out by physiological experiments for application to human beings has long since been discovered, and repetitions are unnecessary and cruel "

No one could charge those gentlemen whose opinions he had quoted with being fanatics or cranks, or with not having the interests of the human race at heart He had studied very carefully the literature which had emanated from the Medical Defence Council on this particular question, and he had also carefully read the correspondence which had taken place not only in medical journals but also in the lay press, and it was most significant that except on one occasion no attempt had been made by opponents of this Bill or by members of the medical profession, to prove that it was necessary in the interests of humanity that vivisection experiments should be made on dogs The single exception was contained in a pamphlet issued by the Research Defence Society which contained an article by Dr Starling, the Foulerton Professor of the Royal Society, in which he made this statement —

> "Why is the use of dogs so essential in medical research? No one will dispute that to gain a knowledge of living functions recourse must be had to living animals and those animals must be such as can be kept in comfort and health within the precincts of a laboratory "

The House would observe that the question of finance entered into the opinion which Dr Starling had expressed He went on to say—and this statement was rather an important one—that —

> "The ordinary farm animals are, therefore, excluded by this fact alone but a more fundamental objection to their use, so far as information to be gained by experiments on them is concerned, arises from the wide differences which exists between the structure, functions and habits of their digestive organs and those of man "

If that contention of Dr Starling was correct it might perhaps be argued that a very strong case was made out against the Bill but this opinion of Dr Starling was in direct opposition to the evidence which was given by one of the greatest medical scientists that this country had ever known—namely, Sir William Osler—before the last Royal Commission on Vivisection, and that evidence was not contradicted by any other medical man or by anyone else Sir William Osler, in his replies to questions, had said that a pig had got a stomach and intestines much more like those of man The pig was used in old days, and he supposed that Galen's experiments were largely upon pigs He had never tried to anæsthetise a pig, but given a pig

After further discussion,

Colonel **Lane Fox** (Secretary for Mines), said that while every hon Member was most anxious to do his utmost to try to reduce the rate of accidents in mines when that was coupled with the assertion in the motion that the Government had failed to carry out their pledges it was obvious that the Government could not advise their supporters to allow the motion to pass, and that an amendment must be moved to put the matter on a better basis The amendment, he thought, expressed the feeling of the vast majority of the House Legislation alone was no use in this matter, and in his belief they had ample legislation They could do far more by regulation, and the Mines Department had been carrying out in the most thorough way by inquiry, research, regulation, and inspection the duties which had been laid upon it The suggestion had been made that the proposed reorganisation of Ministries might involve decreased efficiency in safeguarding the health and safety of miners He could quite safely say on behalf of the Government that that would be far too high a price to pay for any economy In carrying out any economy the House might rest assured that the full interests of the health and safety of those who worked in the mines would be considered, and no rearrangement would be allowed to interfere with that most necessary duty He did not want to say that because this country was in a far better position than any other country, except perhaps France, in this matter that they ought to be satisfied , but at the same time let them not paint the picture too black If they went through the periods of the year they would find that the accident and death-rate was slowly but steadily decreasing They had better try to face facts instead of juggling with figures, which were very dangerous They had set up a Water Dangers Committee which had been travelling round the country and collecting the fullest information from all sources He hoped that that Committee would shortly report They could not legislate in a hurry, and perhaps make a mistake without investigating The Safety in Mines Research Board, which was financed by the Welfare Fund, but was controlled and worked hand in hand with the Mines Department and under its supervision, had a number of daughter committees These committees were dealing with the support of workings underground, with ventilation, explosives, and so on, as well as with wire ropes and spontaneous combustion A new experimental research station had been set up at Buxton which he hoped would be a very great improvement on the former station He hoped that the new station would be officially opened in June, and that its work would be of enormous value to the mining industry At the present time they were already carrying out coal-dust experiments under various conditions, fire damp explosions, and testing mining explosives. In addition, there was a considerable amount of laboratory work being carried on The main laboratory work would continue to be carried on in Sheffield The questions of spontaneous combustion and the use of electricity were not being lost sight of

On a division the amendment was carried by 201 votes to 114

EXPERIMENTS ON ANIMALS

On Thursday, April 28th, Lieut-Colonel **Fremantle** presented a petition signed by leading members of the medical profession concerned in medical education, including 1497 members of university staffs, medical schools, and teaching hospitals, praying the House not to support any Bill to place further restrictions on experimental work on dogs or other animals, and asking for such an alteration in the existing law as would permit, under proper provisions for the prevention of pain, and efficient inspection and control, the use for purposes of research of some of the numerous stray and unowned dogs

FRIDAY, APRIL 29TH

MARRIED WOMEN (EMPLOYMENT) BILL

Sir **Robert Newman**, in moving the second reading of the Married Women (Employment) Bill, said that it proposed to confer on married women the right to work It did not in any way interfere with the legitimate responsibilities and discretion of local authorities It did not compel any public authority to employ a woman because she was married The Sex Disqualification (Removal) Act, 1919, *laid down that* "a person shall not be disqualified by sex or marriage . from being appointed to or holding any civil or judicial office or post" Somehow or other that Act did not seem to have had much effect A woman who was old enough to marry was old enough to decide whether she should continue in her occupation There were hundreds of thousands of women who were earning their own living and he believed that half a million of them were married Therefore it was rather late in the day to bring forward the argument that the place of a woman was in her home There was no justification to refuse the appointment of a married woman because she was married or to dismiss her for the same reason People who objected to the employment of married women as teachers or in the public service forgot that in other walks of life married women were playing a most prominent part He thought he was not wrong in saying that some of the leading lady doctors were married. One found them in Harley-street and other places If a woman could hold a high position in a highly scientific profession like medicine surely it was rather ridiculous to say that she was not qualified to carry out duties in other directions It was rather extraordinary that they should dismiss a school-teacher because she was married, and yet a woman occupied the position of second-in-command of the educational system of the country

Mr **Pethick-Lawrence**, in seconding the motion for the second reading of the Bill, said that what they were really out for in the measure was to secure what they might rightly call the economic charter of the professional married woman. It might be thought that with the growing freedom of women in the country that matters with regard to the employment of married women could be left automatically to right themselves But that was not the case, because with the growth of that independence there was growing up a deliberate attempt to prevent the married woman from retaining her job Therefore it was necessary for the House to take the step contemplated in this Bill so as to secure that these repressive tendencies should be brought to an end Apart from the injury to the woman herself and her husband and family, through the action which they were seeking to get rid of, there was also an injury to the community If, for instance, a municipality had a regulation that no married woman could have a job either as a teacher or a medical officer that municipality and its ratepayers were to that extent deprived of a choice Many of these professional positions entailed a great deal of expense in preparing the individual for the work What an extraordinary waste it was if, because a woman married, the whole value to the community of those years of training was to be thrown away It might happen that a woman on marriage might not be suited or might be prevented by *maternal duties from carrying* out efficiently work which before her marriage she was able to do There was nothing in the Bill which prevented a local authority from dismissing such a woman But they had examples in the medical and other professions which showed quite clearly that many married women and mothers were capable of carrying out efficiently their work, and work quite as arduous as any which the Bill sought to deal with

Mr **Remer**, in moving the rejection of the Bill, said that they must realise the facts There were positions in the public service which it would be utterly impossible for a married woman to undertake There was the possibility of child birth to be taken into consideration, and that must involve long absence from work, and might probably make it impossible for the woman to continue in her employment He also appealed for the rejection of the Bill on the ground of economy If the Bill passed a Government department or municipal authority would either have to pay the woman during the period that she was unable to carry out her work, or if at the time of childbirth she was dismissed there would be much odium on the State or on the municipal authority for carrying out a very distasteful duty The fewer examples they had of legislation of this kind the better it would be for the House of Commons

Captain **Bourne** in seconding the motion for rejection, said that presumably the public bodies who objected to employ married women had good reasons for *their* attitude One reason was because experience had shown that in normal cases a woman was not as efficient a few years after marriage as she was before He did not think that anybody would contend that a woman during the period of pregnancy or immediately afterwards—a period which covered many months—was as efficient as she was under normal conditions Nor was the woman who was looking after a number of small children as efficient *as one* who was not The sexes were not equal in all respects, and no legislation would get over that provision of nature

Sir H **Slesser** said that he objected to interference in contractual relations between employers and employed, but here they were dealing with authorities who were receiving money either from Parliament or out of the local rates There was a distinction between a public body and a private employer, and he believed that it was the intention of the Legislature in passing previous legislation that men and women should be employed or not solely on the grounds of their value to the State, and it was irrelevant to take into consideration the mere fact that they had or had not been married This Bill was a progress in the direction of individual liberty, and for that reason he supported it with great enthusiasm

Viscountess **Astor** said that when she listened to the opponents of the Bill she felt that she knew women who could have twins every year and still be more efficient than some Members of Parliament She hoped very much that

Fatal Accidents in Factories

MR HERBERT WILLIAMS asked the Home Secretary the average fatal accident-rate per 1000 employed reported under the Factory and Workshops Acts during the four years 1922–25 and, for comparison, the corresponding figure for the four years 1910–13 —Sir WILLIAM JOYNSON-HICKS replied · I am afraid I cannot give my hon. friend precise figures, as there are no complete statistics available of the number of persons employed within the scope of the Factory and Workshop Acts in the years mentioned. On the best estimate I can make the fatal accident-rate per 1000 employed was 0 18 per annum for the period 1910–13, and 0 14 per annum for 1922–25 The former figure relates to Great Britain and Ireland the latter to Great Britain only

White Lead Paint Regulations and Ships

MR. RHYS DAVIES asked the Home Secretary whether he had received from the Shipbuilding Federation protests against the regulations governing the use of white lead in paint, what were the objections of the Federation to the regulations, and what steps if any, he proposed to take to see that the regulations should apply equally to the painting of buildings and ships —Sir WILLIAM JOYNSON-HICKS replied · The Shipbuilding Employers' Federation have objected to the application of the draft regulations to the painting of buildings in shipbuilding establishments on the ground that the persons employed in such painting are only occasionally so employed. The painting of ships is not in question, as the Act of last session only applies to the painting of buildings

Secretaries to School Medical Officers

DR VERNON DAVIES asked the President of the Board of Education if the appointment of the 15 secretaries to the school medical officers by the Lancashire education authority had led to any increase in the number of children examined at each session compared with the number examined previous to these appointments, and, if so, what was the increase — Lord EUSTACE PERCY replied If my hon friend will refer to the previous replies which I have given on this subject, he will see that the primary object of the arrangement adopted by the Lancashire authority is not to enable a larger number of children to be examined by the medical officers at each session, but to expedite the necessary clerical work connected with the school medical service I understand, however, that, in fact, the number of children examined per session has increased by about 33 per cent. during the last few years, and that, in the opinion of the authority, if the clerical work were undertaken by the school nurses, the number of children dealt with by the existing medical staff would be reduced.

Imported Machine-skimmed Milk

Lieut -Colonel ACLAND-TROYTE asked the Minister of Health whether he was aware that machine-skimmed condensed milk which was unfit for consumption by infants was being imported in increasing quantities; and whether, if investigations showed that this milk was injurious to invalids and healthy people, he would take steps to prohibit its importation.—Mr CHAMBERLAIN replied I am aware of the increase in the imports of machine-skimmed condensed milk. The absence of milk-fat renders this article unsuitable for infants, but I am advised that its constituents so far from being injurious, are of high nutritional value for ordinary food purposes and I see no sufficient reason for prohibiting its importation.

MONDAY, MAY 2ND

Specialist Officers in India

MR WARDLAW-MILNE asked the Under Secretary of State for India if he was now in a position to publish the full list of miscellaneous and specialist officers in India whose posts it had been decided to treat as superior —Earl WINTERTON replied Certain names have been added to the list already sent to my hon. friend, and it is expected that a further number will be added A premature decision to close the list would result in injustice to officers whose claims have not been disposed of As all the officers whose posts it is decided to treat as superior will be so informed by the Government under which they serve, I do not consider publication in the ordinary sense is required.

Navy, Army, and Air Force Insurance Fund

SIR BERTRAM FALLE asked the Minister of Health if he would consider an amendment to the National Health Insurance Act 1924, so that the period of six months, or in particular cases 12 months, for readmission to the Navy, Army, and Air Force Insurance Fund from date of discharge from His Majesty's Forces should not include any period when a would-be applicant was suffering from mental ill-health, seeing that in a recent case a man regarded himself as perfectly healthy, mentally and physically, yet before another six months had expired he was certified as a lunatic and his child was not eligible for benefit —Mr. CHAMBERLAIN replied The time within which a man discharged from service in the forces may apply for readmission to the Navy, Army, and Air Force Insurance Fund is governed by regulations under Section 59 (1) (*e*) of the National Health Insurance Act, 1924, and legislation would not be required to make the change suggested Although I am not at present satisfied that any hardship arises under the regulation in its present form, I will carefully consider whether any modification in the direction suggested by my hon friend is desirable

Blind Persons in London and Provincial Cities

MR HAYES asked the Minister of Health whether he could give the number of blind persons whose ages were between 50 and 70 years registered in the cities of Liverpool, Manchester, Birmingham, and London respectively.—Mr CHAMBERLAIN replied. The latest figures at present available are those at March 31st, 1925, and are as follows: Liverpool, 476, Manchester, 402; Birmingham, 375; and London, 1346

The Services.

THE HEALTH OF THE NAVY IN 1924

THE statistical report on the health of the Navy for 1924 has just been issued The number of men employed was rather less than in 1923 The amount of illness slightly increased, and the number of deaths rose from 184 to 271 Invaliding fell from 1433 to 1272. There were 65 cases of enteric fever on board the *Royal Sovereign* due to eating lettuce brought on board against orders at Madeira. The figure for pulmonary tuberculosis rose slightly, and there were more invalidings and deaths The incidence of this disease was again highest among telegraphists, the largest increase of cases was among seamen. There were no cases among the sick berth staff Venereal diseases greatly decreased, there were 800 fewer primary cases, and 20,000 fewer days of treatment.

BRITISH GARRISON IN HONG-KONG.

The British Red Cross Society is taking steps to form a branch of the society in Hong-Kong for the benefit of the British troops in the colony. A supply of comforts has already been sent, and a substantial sum has been placed to the credit of the Governor of Hong-Kong for the purchase of such additional hospital comforts as may be required The Army Council have welcomed these efforts on behalf of all ranks of the Garrison, and have expressed their cordial thanks for the prompt and energetic action which the Society has taken.

---

MILITARY NURSING —It is officially announced that Queen Alexandra's Imperial Military Nursing Service and Queen Alexandra's Military Nursing Service for India have been amalgamated as from Nov 1st, 1926 The normal tour of duty in India for members of the amalgamated service below the rank of principal matron will be five years under an anæsthetic he agreed that it would be a very useful animal to operate on. The late Sir Frederick Treves[1] said:—

> "Many years ago I carried out on the Continent sundry operations upon the intestines of dogs, but such are the differences between the human and the canine bowel that, when I came to operate upon men, I found that I was much hampered by my new experience, that I had everything to unlearn, that my experiments have done little but unfit me to deal with the human intestine."

The Royal Commission did not report in favour of the exemption of dogs, but that exemption was only lost by a very small majority. When the question was before the Commission Sir William Osler said: "I think we have all felt that it would be very much better if we could get animals other than the dog to operate on." He quoted with approval the opinion of Dr. Cushing to the effect that

> "There is naturally a feeling of regret in the minds of many—of none greater than our own—that animals, particularly dogs, should be subjected to operations even though the object be a most desirable one and accomplished without the inflicting of pain, and did expense permit we would gladly have used animals with which there is an association of less acute sentiment on the part of all."

In some of the letters which had appeared in the press doubt had been expressed whether under the safeguards which were imposed animals actually suffered pain in consequence of these experiments. He did not think that any member of the medical profession would dispute that in many cases very great suffering was involved to the animal. It was clear from the report of the Commission, and from the evidence given by the Home Office expert, that there was a great deal of pain and suffering in certain cases. He would like to quote the opinion of Dr. George Wilson, medical officer of health for Warwick, and a member of the Royal Commission on Vivisection, and President of the State Medicine Section of the British Medical Association. The statement was from his presidential address to the British Medical Association at Portsmouth in 1898:—

> "I boldly say that there should be some pause in these ruthless lines of experimentation. I have not allied myself to the anti-vivisectionists, but I accuse my profession of misleading the public as to the cruelties and horrors which are perpetrated on animal life. When it is stated that the actual pain involved in these experiments is commonly of the most trivial description, there is a suppression of the truth, of the most palpable kind, which can only be accounted for by ignorance of the actual facts. I admit that in the mere operation of injecting a virus, whether cultivated or not, there may be little or no pain, but the cruelty does not lie in the operation itself which is permitted to be performed without anæsthetics, but in the after effects. Whether so-called toxins are injected under the skin into the peritoneum, into the cranium, under the dura mater, into the pleural cavity, into the veins, eyes or other organs—and all these methods are ruthlessly practised—there is long drawn out agony. The animal so innocently operated on may have to live days, weeks or months, with no anæsthetic to assuage its sufferings, and nothing but death to relieve."

He would also quote the opinion of Dr. Fielding-Ould, who was a medical man upon whose word the greatest authority and weight could be placed. He said:—

> "Consider a case of 'brain surgery' in which after removal of part of the brain the animal is allowed to regain consciousness and subsequently to drag out weeks of a painful convalescence. It is apposite also to mention cases in bacteriological work, to which no reference is made by Sir Charles Ballance. Often it happens that in the interests of research an emulsion of a virulent germ is injected into the abdominal cavity of a living animal (without an anæsthetic) and the creature is left to develop the disease with all the agonising accompaniments of peritonitis."

That letter was written by Dr. Fielding-Ould on March 30th of this year. He had also a large number of extracts from THE LANCET, the *British Medical Journal*, and other journals, giving particulars of operations and experiments which had been performed during the last year or so, and which showed beyond any question that these unfortunate animals which were experimented upon did suffer great agony and misery. He appreciated the fact that it was too late in the afternoon for him to get a second reading of the Bill that day, but he hoped that it might be possible to get the Bill passed some time during the session.

Lieut.-Colonel **MOORE**, in seconding the motion for the second reading, said he must disassociate himself from any views expressed by antivivisectionists. He was not an antivivisectionist. He was ready to accept the view that vivisection was necessary for the protection and extension of human life, but what he was not satisfied about was that dogs as such were necessary for these experiments, and that the vivisection of dogs would actually result in the saving or extension of human life. It was as a dog lover that he was addressing the House, and in taking this action he was confident that he was representing a growing body of opinion outside the House which regarded with horror the vivisection of dogs, and looked upon it as a blot upon the highly developed civilisation of the twentieth century. The chief argument used by vivisectionists in favour of the practice was that experiments on animals, including dogs, were justified and necessary in order to ascertain the probable effects of such experiments on human beings, and so save suffering and prolong human life. Were that contention proved to his satisfaction he would not have another word to say on behalf of this Bill. But had it been proved? Prof. Lawson Tait, Fellow of the Royal College of Surgeons, said: "The fact is that diseases of animals are so different from those of men that the conclusions of vivisectionists are absolutely useless."

Lieut.-Colonel **FREMANTLE**: In what year did he say that?

Lieut.-Colonel **MOORE**: I cannot say off-hand.

Lieut.-Colonel **FREMANTLE**: Twenty-five years ago.

Lieut.-Colonel **MOORE** said that he submitted that a learned gentleman's statement did not alter with the passage of time, more especially in the medical profession. Doctors, he assumed, had certain permanent professional beliefs. In confirmation of that statement he would take a few of the diseases for the cure of which vivisection experiments were being carried on. In the last 20 years the death-rate from cancer had increased by 46 per cent. In the same period the death-rate from diabetes had increased by 55 per cent., and the death-rate from thyroid diseases had increased by 85 per cent. These were diseases which vivisection was intended to relieve and cure. Let him take, on the other hand, diseases the cure of which largely depended on open air and more hygienic conditions of life. They found the enteric death-rate in 20 years had gone down by 80 per cent., measles 60 per cent., and scarlet fever 77 per cent. These were startling figures. Though he was not prepared to accept these figures as conclusive proof that vivisection was useless, he suggested that they called for very serious consideration, and at any rate provided an adequate case for the exemption of dogs from vivisection.

Lieut.-Colonel **FREMANTLE** moved the rejection of the Bill. He said that it was impossible to state the case against the measure in the quarter of a minute which remained, but he wished to say that they could meet the arguments put forward that day and would be glad to do so at any other time. If any antivivisectionists or people in favour of the Bill wished to have a meeting in that House or anywhere else, they would be glad to meet them on even terms, and they would beat them every time.

Sir **RICHARD LUCE** rose to speak, but it being 4 o'clock the debate stood adjourned.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 27TH

Passage Concessions to Indian Medical Officers

Mr. **PETHICK-LAWRENCE** asked the Under Secretary of State for India whether a decision had now been reached as to granting passage concessions to Indian officers who entered the Indian Medical Service by competitive examination in London.—Earl **WINTERTON** replied: My noble friend has decided that all officers of the Indian Medical Service, including those of Asiatic domicile, shall be required before promotion to the rank of major to complete the senior officers' course at the Royal Army Medical College, Millbank. Attendance at this course will count as duty and carry with it free passages to and from the United Kingdom. Officers of the Indian Medical Service of Asiatic domicile will immediately after completing this course be regarded as eligible for a period of study leave, during which they will retain a lien on their free return passage to India. Those officers of Asiatic domicile now on service, who by reason of their age are disqualified from attending the senior officers' course, will be eligible once during their service for a free passage to England and back when proceeding on study leave. The Government of India have, however, not found it possible to give full effect to the scheme in the present financial year.

THURSDAY, APRIL 28TH

Pensioners and Final Awards

Sir **WALTER DE FRECE** asked the Minister of Pensions the number of applications for increase of pensions by men suffering from admitted war disabilities who did not appeal against their respective final awards within the statutory period, but whose condition had now become admittedly worse; and how many such men were actually under treatment, although their pensions could not be increased.—Major **TRYON** replied: I have no record of the number of cases of the kind referred to, but according to all the information in my possession they are comparatively few. With regard to the latter part of the question, I would remind my hon. friend that in every case where, following a course of medical treatment and observation, it is found that a serious and permanent error was made in the final award, a further grant is made under special sanction.

---

[1] Brit. Med. Jour., Nov. 5th, 1898.

mixed with many other oxidation products of glucose, some of which are toxic Thannhauser and Jenke treated cases of severe diabetes with the commercial product, and found that it cleared up the urine from sugar and acetone bodies, but its use could not be continued because of gastro-intestinal complications Pure glucosone, made by Fischer's method, does not appear to give rise to any bad effects beyond those immediately produced from an overdose, but this method of preparation is costly and complicated Only small quantities of the pure substance have been hitherto available, and for that reason the experiments recorded by Dr Hynd have been carried out on mice Rats and rabbits, however, show the same effects on administration of an overdose, and the symptoms are remarkably similar to those which follow an overdose of insulin

Hitherto there have been many attempts to find a substitute for insulin, but few have been directed to ascertaining what form of carbohydrate other than glycogen results from the action of insulin upon glucose If it can be established that glucosone is an important intermediate its importance is obvious

CREAM IN INFANT FEEDING

To the Editor of THE LANCET

SIR,—Dr R C Jewesbury, in the concluding paragraph of his letter, asks for information on the point "whether fat is needed rather for its vitamin content than for its food value," and adds, "until we are better informed surely we must believe that it is of value from both these points of view" All the available evidence goes to show that fats, apart from their high caloric value, have no specific food value, such as carbohydrates, for instance, possess by virtue of their so-called "protein-sparing action," and that no advantage is derived from a high intake of fat On the contrary, the experimental work of Colonel R McCarrison [1] indicates that a high intake of fat may have an unfavourable effect on the function of the thyroid gland, unless it is corrected by a corresponding increased intake of iodine

I am, Sir, yours faithfully,

W CRAMER

Imperial Cancer Research Fund, Queen square, W C,

BROMSULPHALEIN

To the Editor of THE LANCET

SIR,—Dr Rosenthal's surprise at my results was no greater than my own disappointment He himself explains the reason that great difficulties existed in the manufacture of the dye, and Mr W. Martindale—the "local chemist"—prepared a substance differing in very slight degree from the original prepared by Dr E C White As there are, however, grave doubts as to whether this substance behaves in a similar way to White's preparation I am reinvestigating the whole matter with bromsulphalein kindly supplied to me gratuitously by Dr White and by Messrs Hynson, Westcott, and Dunning, of Baltimore If I have been led into erroneous conclusions I shall take the first opportunity of contradicting them, but at the present time I am keeping an open mind upon the subject In conclusion, I may add that I have been in communication with Dr White about the chemistry of these dyes, and his letter threw the first doubts upon the dye which I had used

I am, Sir, yours faithfully,

ERNEST BULMER, M D, M R C P

Birmingham, April 15th, 1927

THE PENALISATION OF THE TUBERCULOUS

To the Editor of THE LANCET

SIR,—Dr Varrier-Jones has misunderstood the purpose of my letter My meaning would, perhaps, have been clearer if my remarks had been entitled "The Penalisation of the Notified" I do not know anything about the gentleman who was refused a post in a sanatorium because he had been treated for tuberculosis, further than was to be gleaned from "M O's" letter in your issue of March 19th, but I gathered that he had been advised to be treated for this affection and had made a good recovery

It does not always follow that when a patient in the early and curable stage of the disease is advised to be treated in a sanatorium that this advice is taken; the patient concerned preferring to take the risk of getting better as best he may, and if this should happen, having avoided notification, or at least publicity, will suffer no disabilities, but will be regarded as an ordinary citizen To illustrate what I mean, I may say that some years ago my advice was asked as to what had better be done with a young police-constable who was suffering from hæmoptysis, who, by the way, had also tubercle bacilli in his sputum I replied that he should be sent to the sanatorium at once as no one was justified in risking this man's life because he might lose his job if he admitted that he was suffering from tuberculosis, but I pointed out that in my opinion there was no reason why he should not be reinstated if he made a good recovery, this course was followed and after an uneventful recovery taking five months, he was taken back into the force, having lost his tubercle bacilli, and has been doing duty ever since

My letter was in no way concerned with the well-known fact that many cases of chronic disease can be kept alive and working for many years if their surroundings are favourable, indeed, there are thousands of chronic cases of tuberculosis carrying on their ordinary avocations, suffering from tuberculosis often in complete ignorance as to the nature of the disease from which they are suffering A sanatorium should not, however, be concerned with these cases, but should spend its time in preventing the formation of persons chronically ill, but in order that this may happen it is necessary that the public should be well assured that no penalties shall follow when they elect to make a proper effort towards recovery instead of hiding the nature of their illness lest a worse fate befall them It is obvious that no question of continuing work during treatment will arise in such cases

I am, Sir, yours faithfully,

April 21st, 1927 ERADICATION

THE TITLE OF DOCTOR—By a judgment of Mr. Justice Middleton, osteopaths and manipulative surgeons in the province of Ontario are debarred from using the prefix "doctor" as an occupational designation Under the Ontario Medical Act the use of the term "doctor" is forbidden to all except registered physicians

NOTTINGHAM HOSPITAL—On Saturday last Princess Mary opened the new out-patients' department of Nottingham General Hospital and an extension of the Children's Hospital The ground floor of the out-patients' wing of the General Hospital includes four blocks of consulting rooms, dressing rooms, and examination rooms The upper floor consists of a complete nose, ear, and throat hospital with 40 beds, an operating theatre and other adjuncts, the basement contains a fully equipped department for radiography, ultra-violet ray and therapeutic treatment, and a complete orthopædic department, with a gymnasium The extension has cost close upon £100,000, of which Mr W G Player has given £50,000 The Children's Hospital has been so much enlarged and improved that it is virtually a new building, connected by a corridor with the original, which is eventually to become a nurses' home There are 78 beds in six wards, ample provision is made for open air treatment, and there are playgrounds on the [illegible] Player has given £10,000 towards the cost

"Audi alteram partem"

TESTS FOR DRUNKENNESS

To the Editor of THE LANCET

SIR,—Reverting to Sir William Willcox's letter in your issue of April 23rd, I had thought that our discussion at the Medico-Legal Society had disposed of the objection, faintly raised by someone, that there might be legal difficulty in carrying out Dr Southgate and Dr Carter's method But Sir William Willcox now writes in your columns, "there were definite legal objections to the application of the test by the prosecuting authority—for example, the taking of a sample of blood from an accused person who was unwilling might be technically regarded as a legal assault" To take a sample of blood, yes, if it meant making an incision to obtain it, but we were talking about a sample of urine, and the taking of that would not involve a trespass, and it would provide legal evidence The method proposed by Dr Southgate and Dr Carter was, I understand, to have a urinal in the cell, with its waste pipe running outside, from which the sample could be collected

I am, Sir, yours faithfully,
ERNEST E WILLIAMS.

Lake road, Wimbledon, S W, April 29th, 1927

THE TOXÆMIA OF ACUTE INTESTINAL OBSTRUCTION

To the Editor of THE LANCET

SIR,—It astonishes me that Mr B W Williams in his Hunterian Lecture on the above in your last issue should have omitted all reference to the very careful work performed by McQuarrie and Whipple on the cause of the Toxæmia of Acute Intestinal Obstruction McQuarrie and Whipple performed experiments which appeared to show that the toxæmia in question is due to the absorption of a toxic proteose from the obstructed gut, and they even injected proteose into the veins of normal dogs and produced all the signs and symptoms of a toxæmia comparable with those found in acute intestinal obstruction If an individual believes that A is equal to B, to substantiate his hypothesis, besides giving reason to believe that this is so, he must also display the error in the arguments of all those who have shown, or apparently have shown, that A is not equal to B Mr Williams believes the toxæmia of acute intestinal obstruction is due to absorption of toxin produced by the multiplication of the *B welchii* in the obstructed gut, that it is due to the absorption of toxic proteose he does not seem to have considered, and he does not show or state that the toxin in question is in fact a toxic proteose Moreover, he states his opinion in spite of allowing that "the characteristic toxæmia will develop when there is paralytic ileus, whatever the cause of the peritonitis, whether streptococcal, pneumococcal, or resulting from any organism, when *B welchii* is not present in the peritoneal infection"

That Mr Williams should not have referred to my work is less surprising, yet are my unorthodox views supported by argument and scientific inquiry I showed, as a reviewer of my work allowed, that McQuarrie and Whipple had not sufficiently considered the effect of the persistent vomiting, induced either by strangulation of the intestine or by the injection of certain proteoses into the blood stream of normal animals, on the individual But Mr Williams refers not at all to the reaction of the patient to an obstruction of his intestine He imputes the "fine fatty degeneration in the liver and heart muscle" to the *B welchii* toxin, he has not considered whether such changes may be produced by the persistent vomiting Yet there is reason to believe that persistent vomiting, even in the absence of intestinal obstruction, can cause such changes, indeed, in the pernicious vomiting of pregnancy we have such a picture The effect of the persistent and frequently recurring pain, the restlessness, sleeplessness, the straining and the persistent vomiting of all patients suffering from intestinal obstruction is absent from his drawing, he imputes all the changes to the absorption of a toxin In spite of that he has not shown the presence of the toxin in the blood in these cases, he has not even shown that such is absorbed and even admits that "the organism may be abundant in the large intestine without any clinical toxæmia", and he allows that in acute obstruction improvement usually follows rapidly on successful operative relief But if the toxins are in the blood and working their wicked will, operative interference should be far less effective than it is

That organisms, even pathogenic ones, are present in the obstructed gut we may well believe The offensiveness of the vomit is sufficient evidence That a filtrate of such vomit injected into mice should kill them, and that mice protected from such toxin by an antitoxin should survive, we may well believe But this does not show that such toxins are absorbed from the obstructed gut and give rise to all the toxæmic phenomena and the collapse of intestinal obstruction. The multiplication of these organisms in the obstructed gut is readily explained by the limitation of blood flow through, and the diminished activity of, the mucosa in the affected part So far from their being absorbed, there is reason to believe that such gut contents are not absorbed or not in normal amount or at normal rate Mr Williams seems to admit as much, referring to the sudden collapse which may occur unexpectedly after successful operation, he says this may be due to "the sudden flooding of the circulation with a lethal dose of toxin by the very act of relief of the strangulated intestine through restoration of the circulation to the damaged area permitting very rapid absorption of toxin, or possibly by rapid absorption of toxin by the normal mucous membrane distal to the obstruction after its relief" The katabolic processes in the body, which in intestinal obstruction are occurring at speed, are forgotten or not considered, that man is an animal subject to fatigue—even in acute intestinal obstruction—is a phase of the question completely ignored —I am, Sir, yours faithfully,

R H PARAMORE, F R C S Eng

GLUCOSONE A POSSIBLE SUBSTITUTE FOR INSULIN

To the Editor of THE LANCET

SIR,—A paper[1] communicated to the *Royal Society* recently by Dr Hynd from this department may turn out to be of considerable importance Dr Hynd has ascertained that glucosone or aldofructose, one of the oxidation products of glucose or fructose, produces when injected subcutaneously in mice a condition which is very similar to that produced by the injection of insulin Similar oxidation products of maltose and lactose—i e, maltosone and lactosone—are inactive, but on hydrolysis become active Dr Hynd suggests that glucosone is the intermediate in carbohydrate metabolism which is normally formed, and that some at least of the symptoms produced by insulin are due to the production of glucosone in excess The symptoms are modified by adrenalin and pituitrin as are those due to insulin

If Dr Hynd's views are correct it is possible that glucosone might be used in place of insulin, particularly as it can be taken by mouth Preparations made commercially were used in Germany by Thannhauser and Jenke, but they were prepared by the hydrogen peroxide method which gives a product

Obituary.

ERNEST HENRY STARLING C.M.G., M.D., F.R.C.P. LOND., F.R.S.,

FOULERTON RESEARCH PROFESSOR OF THE ROYAL SOCIETY

WE deeply regret to announce the death which occurred this week in Jamaica of Prof. Ernest Henry Starling, the distinguished physiologist, whose name is a household word in medicine in all countries of the world. He died on board the *Ariguaing* as the ship was nearing Kingston, the voyage having been taken for the benefit of his health, which had been indifferent for some time, although he did not allow this fact to interfere with the strenuous routine of the winter session. He had worked with characteristic intensity until very shortly before his departure, and it was hoped and believed that a few weeks' rest on board ship in a warmer climate, which he loved so much, would restore him, as it had done on previous occasions, to his customary vigour.

PROF. E. H. STARLING

Ernest Starling was the eldest son of a barrister who practised in Bombay and wrote a work on Indian legal procedure. He was educated at King's College School and, completing his medical course at Guy's Hospital, graduated in medicine at the University of London in 1888, after a brilliant career as a student, being exhibitioner and gold medallist at the University in physiology and chemistry, and University scholar in forensic medicine, while he also won the gold medal in botany of the Apothecaries Society. He was further helped substantially by the Grocers' Scholarship and a scholarship from the British Medical Association. He proceeded to the M.D. degree in 1890 when he qualified for the University gold medal, and having continued his studies at Heidelberg under Kühne resolved to pursue physiology as a career. He held certain house appointments but became demonstrator of physiology at Guy's Hospital in 1889 and joint lecturer in the subject in the following year, and for the next nine years he lectured on physiology in the medical school at Guy's, and also at the School of Medicine for Women. During this period he found time to study under Heidenhain in Breslau.

Starling's early career was much influenced by Leonard Wooldridge, who, returning to London from a visit to Ludwig at Leipzic, was fired with the newest and best ideals of experimental physiology; Starling worked with Wooldridge, and on the latter's early death was appointed to succeed him at Guy's, and was thus launched as a physiologist. The teaching of Heidenhain brought early fruit, for it was in consequence of this association that Starling took up the study of lymph formation to which he made important contributions, largely by the application of recently discovered data in the realm of physical chemistry. Starling taught physiology, and virtually created as well as ran the department of the subject at Guy's Hospital, from 1889 until he left Guy's to succeed Prof. Sharpey-Schäfer as Jodrell Professor at University College, London, in 1899.

At University College his achievements were of the highest, and his work for it and for the University of London was untiring, both single-handed and in association with his brother-in-law, William Bayliss. Always a high idealist he did everything to promote scientific work, not only in physiology but in many other departments of scientific activity, as is illustrated by the fact that he became a member of the governing body of the Lister Institute from the outset and at his death had served thus for 20 years. At University College he planned and constructed the Institute of Physiology—a remarkable feat—and he also conceived the general scheme of the present block of medical science laboratories with their own central library, which was subsequently made possible by the bequest from the Rockefeller Foundation.

A summary of Starling's scientific work must be attempted, though its far-reaching and prolonged nature must make such a notice imperfect. His earliest published work was on electric currents in the mammalian heart and was written in collaboration with Bayliss in 1891, with whom in 1892 he also wrote on the parts of the heart affected by the sympathetic and accelerator nerves. In 1893 came a paper based on work done in Heidenhain's laboratory on the action of lymphagogues. He continued this work on lymph formation at Guy's, and during the next two years obtained results on which most of our present knowledge of capillary permeability and lymph and œdema formation depends. These researches introduced the fundamentally new idea that the rate of transudation was a function of the colloidal osmotic pressure on the one hand and the hydrostatic pressure on the other. This was followed by a series of papers on the action of lymphagogues and on the absorption of fluids from tissue spaces and serous cavities; this work led naturally to his investigations in 1899 of the glomerular functions of the kidney, in which he was led to the determination of the colloidal osmotic pressure of the blood-serum. This work synchronised with his election to the Royal Society. Much of his work between the years 1891–1905 was done in collaboration with Bayliss. This included their joint work on the innervation and movements of the intestines, and the mechanism of the secretion of pancreatic juice, which included the discovery of secretin in 1902, and which opened up new avenues of investigation which are still being explored. The next phase was the exact analysis of the action of asphyxia, especially on the circulation; this began about 1909 and ultimately led to the perfection of the heart-lung circulation preparation with which a great deal of his subsequent work was done. This preparation enabled the experimenter to control the mechanical conditions of the heart to an extent which had not previously been possible. and the research which was carried out by Starling and numerous professors, which is still in progress, led to the laboratories at University College becoming the focus for the work. It involves not only a detailed investigation of the mechanical conditions of the heart beat, but also is extended to include investigations of the coronary circulation and of the mechanism by which the rate and output of the heart is subjected to control.

THE IRISH FREE STATE MEDICAL REGISTER BILL

(FROM OUR OWN CORRESPONDENT)

THE text of the Free State Medical Register Bill, which was introduced to the Dail by President Cosgrave last week, was published on Monday last It provides for the confirmation of an agreement made between the British Government, the Government of the Irish Free State, and the Government of Northern Ireland, on the subject of medical registration and for the establishment of a Medical Council and a Medical Register for the Irish Free State

The agreement, which is signed by Earl Balfour, Mr McGilligan, and Sir Dawson Bates, on behalf of the respective Governments, provides that the powers and functions of the General Council in regard to Ireland, and the powers formerly vested in certain universities and corporations in Ireland, shall be deemed not to have been affected by the establishment of the Irish Free State or of Northern Ireland The nomination of members of the General Council by the several universities and corporations in Ireland shall be made as heretofore, as shall the election of a direct representative by registered practitioners in Ireland The nomination of a member for Ireland, formerly made by His Majesty, shall in future be made by His Majesty on the recommendation of the Government of Northern Ireland It is further provided that any person who is or shall be registered in the General Register shall be entitled, on payment of a fee prescribed by the Free State Parliament, to be registered in the Free State Register, no fee shall be payable by any person who, being on the General Register at the date of establishment of the Free State Register, applies for registration therein in the prescribed time and manner Apart from the agreement with Great Britain, the Bill sets out the constitution, powers, and duties of a Medical Council to be established in the Free State The Council is to consist of nine members—namely, one nominated by the Executive Council, one each by the following bodies University College, Cork, University College, Galway, University College, Dublin, the University of Dublin, the Apothecaries' Hall, one nominated jointly by the Royal College of Surgeons and the Royal College of Physicians, and two, who shall be registered medical practitioners, elected by the registered medical practitioners resident in the Free State The Council will have, as its chief duty, to establish and maintain a Medical Register Persons entitled to be registered on the Register, on its establishment, and without the payment of a fee, will be —

(*a*) Every person already registered in the General Medical Register and resident in the Free State, and (*b*) every person resident outside the Free State and already registered in the General Medical Register who applies to the Free State Council within one month after the establishment of the Register

After the establishment of the Register, the following persons, on making the prescribed application and paying the prescribed fee, shall be entitled to be registered in it —

(*a*) Every person who at the time of application is registered in the General Medical Register, and (*b*) every person who at the time of application possessed one or more of the qualifying diplomas mentioned in the third schedule to the Bill—viz, L.R C P I, L R C S I, Licentiate of the Apothecaries' Hall, Dublin, M D, Dublin University, M B, B Ch, Dublin University, Licentiate in Medicine and Licentiate in Surgery, Dublin University, M D N U I, M B, B.Ch N U I

On and after the establishment of the Free State Register no practitioner shall be entitled to recover in any legal proceedings any fees on account of medical or surgical attendance by him unless he was registered in the home Register at the date on which such attendance was given

Similarly, appointments which are to be held by "qualified medical practitioners" or "registered medical practitioners," will only be tenable in the Free State by persons on the Free State Register

The Bill gives the Council the same powers as regards education and discipline as are at present possessed by the General Council Any persons aggrieved however, by an adverse decision of the Council, will have the right of appeal to the High Court, the judgment of which shall be final, and not subject to appeal to any other Court

The necessary expenses of the Council for the first year are to be borne by public funds, and subsequently out of the Council's own monies

Up to the present there has been little time for comment on the Bill It seems to be clear that there is no interference with the privileges and rights of Irish graduates and licentiates to registration on the General Register, and therefore, on the main point the fears and anxieties of the Irish medical profession at the time when it was announced that a change would be made can now be allayed It has to be admitted, however, that the medical profession paid hardly enough attention to the question of the constitution of the Free State Medical Council, and no discussion took place at any time between the representatives of the profession and the Government on the subject The result is a singular confusion of procedure The Bill departs from the principle of constitution of the General Council, by which each licensing body, whether university or corporation was entitled to one member It seems to adopt the principle of assigning one member to each school instead of to each licensing authority, but even this is thrown over, for one corporation which has no relation to a school is given a member. The result is neither logical nor possessed of practical merits The principle underlying the constitution appears to be sound and not to be inconsiderately abandoned The Council has to deal with the licensing body, rather than with the teaching body directly It is for the body that grants the diploma to satisfy itself of the adequacy of the teaching which prepares for the diploma The General Council has frequently inspected examinations, but has never thought it its duty to inspect teaching In this respect the present Bill follows the same principle, for it gives power to the Medical Council to inspect examinations but none to inspect teaching There seems to be no justification for the bringing of teaching institutions as such into direct relation with the Council On the other hand, the grouping together of the two Royal Colleges for the nomination of one member seems an unnecessary economy Probably a majority of practitioners in the Free State at present are on the Register by virtue of the possession of the diplomas of these bodies Moreover, they are the only purely professional corporations in the Free State concerned with the qualification of medical practitioners, if one excepts the Apothecaries' Hall, the other licensing bodies being non-professional, such as the universities It is undesirable that the lay element should have a supreme control in matters of medical education On the Free State Medical Council as proposed in the Bill, five members out of nine will be appointed by lay authorities

The right of appeal to the High Court is interesting, but is not likely to give rise to much opposition

---

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL —At the annual Court of Governors, Mr H E West, the deputy chairman, said that the worst legacy the hospital had ever inherited was its cumbersome and little understood name, and that it would continue to be hampered by it "unless someone invented a good slang one" It was reported that the work at the country branch at Stanmore had exceeded expectations, and that £78,000 had been raised towards the £115,000 needed for extension there There was an increase during the past year of more than 4000 in the number of out-patient attendances The weekly cost of an in-patient at Stanmore is £1 13*s* 9*d*, about 14*s* per week less than in London

Collingridge volunteered for service as surgeon with the Serbian forces In spite of his youth he was given responsible work in the organisation of hospitals and at the end of the campaign received the Order of Takova from King Milan After his return to England he qualified as M R C.S Eng in 1877 from St Bartholomew's Hospital. and graduated both in law and medicine at Cambridge later being called to the Bar as a member of Gray's Inn Two years of private practice followed after which in 1880 he was appointed medical officer of health for the Port of London. During the 20 years he held this office there was great advance in the practice of port sanitation and Collingridge's part in the development of London's protective health service was a large one His work was both responsible and difficult and was the more conspicuous because during two continental epidemics of cholera he had to devise measures for guarding against the spread of the disease to this country. Problems of this kind interested him greatly, and he chose Quarantine as the subject of his Milroy Lectures,[1] delivered in 1897 before the Royal College of Physicians, in which he made an effective attack both upon the theoretical basis and practical application of the measure It was not one, he said, that could usefully be enforced by a commercial country; it was expensive it led to a false sense of security and it involved serious danger to health from the detention of vessels in conditions that were often insanitary and kept people within range of infection. Sanitation and a rational system of medical inspection must prove more efficacious and less burdensome Dr. Collingridge also showed himself a warm advocate of better conditions of life for the mercantile marine and a good deal of the work which is gradually leading to their improvement has been done by men who became familiar with the work which won praise for his department In 1901 he was transferred to the post of medical officer of health for the City of London in succession to Dr. Sedgwick Saunders, and here also before his retirement in 1913. he was successful in his work for the public health Not all his schemes were carried through without opposition, and at times he had to face a great deal of criticism, especially in regard to his crusade against the unclean conditions in which the oyster was bred and distributed for the London market. He did the same service for the cockle—the poor man's oyster as he called it

Outside his official duties Dr. Collingridge was a keen soldier. At Cambridge he joined the University Rifle Corps, and on coming to London he was for ten years a member of the Honourable Artillery Company His later service included seven years with the Volunteer Medical Staff Corps and eight years as officer commanding the Militia Medical Staff Corps Throughout the late war he was in charge of Auxiliary Military Hospital 112, in Kent He lived for a long time in this county but later moved to Berkshire where he became a justice of the peace The end of his life was spent at Pennington, in Hampshire

Dr Collingridge was a Knight of Grace of the Order of St John of Jerusalem He married a daughter of Captain Thomsett C M G R.N

POST-GRADUATE COURSES AT BERLIN—A series of international post-graduate medical courses will be held at Berlin from Sept 15th to Oct 31st under the auspices of the Kaiserin Friedrich Haus and with assistance from the medical faculty of the University The medium of instruction will be German but a number of lecturers speak English and other languages Information about accommodation expense of maintenance and facilities for attending at clinics and hospitals may be had from the office of the Kaiserin Friedrich-Haus 2-4 Luisenplatz, Berlin N W 6 The office is willing to send particulars of German post-graduate instruction besides the short courses held between the above dates

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON—An ordinary Comitia of the College was held on April 28th, the President, Sir John Rose Bradford being in the chair. The following candidates, having satisfied the Censors' Board, were elected as members —

Drs Eric Harold John Berry, Sohan Lal Bhatia, George Frederick Buchan Arthur Burrows, Robert Greenhill Cochrane, Elizabeth Mary Cowie, Edward Charles Dodds, Alfred Claude Mitchell Elman, John Bell Ferguson, Frederick James Theodore Foenander, Ian Wolfe Gallant, Dorothy Gibson, Arthur Cecil Hampson, Alan Trevor Jones, Georges Klionsky, Allan Dunstan Lamphee, Joseph Tegart Lewis, Frederic Ernest Loewy, John Allison Macfadyen, Eugene McLaughlin, Peter Henry Martin, Peter Milligan Henry Seaward Morley Cyril Thomas Piper, Alice Campbell Rose, Leonard Victor Snowman, Saravanamuttu Somasundram, Thomas Harold Thomas, and Neil Thorburn Melrose Wigg

The following were elected to the Fellowship on the nomination of the Council —

Drs William Smith Paget-Tomlinson, George Hall Donald Elms Core, Henry Pratt Newsholme, Arnold Walmsley Stott, Georg Herman Monrad-Krohn (Christiania), Thomas Henry Gostwyck Shore, Vivian Bartley Green-Armytage, Reginald St George Smallridge Bond, Maurice Davidson, Thomas Izod Bennett, Edward Mapother, Charles Frederick Terrence East, and Hugh Maclean

Nominated by Council under By-law XXXVII (*b*). Dr Andrew Balfour and Sir Squire Sprigge

The Registrar moved for the first time the following temporary by-laws, both of which were passed —

1 That Georg Herman Monrad-Krohn, being resident in Norway, be admitted to the Fellowship *in absentia*, any by-law to the contrary notwithstanding

2 That Vivian Bartley Green-Armytage being resident in India, be admitted to the Fellowship *in absentia*, any by-law to the contrary notwithstanding

Licences to practise were conferred upon 164 candidates (135 men and 29 women) who have passed the Final Examination in medicine, surgery, and midwifery of the Conjoint Board and have complied with the by-laws of the College. The following are the names and medical schools of the successful candidates —

V. H Addison, St Bart 's, B W Alexander, Cambridge and St Bart.'s, Sophia A P Allen, Charing Cross, R. G. Apthorpe, Cambridge and St. Thomas's; H E C Aslett, St Mary's H Aziz Manchester, J D Bailey St. George's; W. B Ballenden, Birmingham. G H Barendt, Cambridge and St. Bart.'s, J F. During the last few years he was employing the heart-lung circulation as a means of investigating the mystery of urinary secretion

Starling's practical work was admirably illustrated in his literary activities, books, lectures, and addresses His first book, the "Elements of Human Physiology," was recognised at once to form a compact and all-round exposition of the main facts and theories of the science as then accepted, it formed a safe guide for the student and a good foundation for all on which to raise a superstructure of the knowledge obtainable from the study of more elaborate text-books, and, as edition followed edition, the results of general or special research were duly incorporated A "Primer on Physiology" followed in 1904, in which a small volume, priced at 1s, actually conveyed to the reader the broad features of the functions by which life is maintained The message that a knowledge of fundamental facts in physics and chemistry must be possessed before the complex processes carried on in the living body can be rightly observed or recognised as being manifestations of the laws of nature, was the text of all Starling's written work, and those who read the "Primer" in the early stage of their medical curriculum will remember how much it enabled them to follow with intelligence extended accounts of the physiological functions when placed before them in lectures The same method of argument was] followed in the Arris and Gale Lectures which he delivered before the Royal College of Surgeons of England in 1896, taking as his subject the physiological factors involved in the causation of dropsy In these lectures he sketched the working in the normal animal of the processes of lymph production and lymph absorption, and proceeded to examine in detail the causation of dropsy, thus expounding the reasons, chemical and physical, which lay behind the pathological manifestations, and dictated the course of treatment and the technique adopted

In 1897 Starling was elected a Fellow of the Royal College of Physicians of London, and in 1905 delivered the Croonian Lectures In these he described the chemical correlation of the functions of the body, and vindicated the assumption, which is the basis of scientific medical practice, that the activities of the body are coordinated among themselves by the production and circulation of chemical substances The descriptions of the classic investigations justifying the thesis were so clear that they must have formed for many medical men an introduction to far more strictly scientific views than they had previously held, or furnished them with the scientific reasons for the therapeutical procedures which they adopted In the fourth of these lectures, Starling discussed the influences of the generative organs on the body as a whole, and on its parts, describing the researches with which Dr Lane-Claypon was associated, and which introduced hormones to the general medical reader

Shortly after came the discovery of secretin by Bayliss and Starling, and in Starling's last public delivery will be found his estimate of the meaning of that work[1] The occasion was the first of the lectures delivered in connexion with the centenary celebrations of University College, London, in which Starling briefly reviewed a century of physiology, giving a masterly survey of the progress of the science from the time of Harvey to the third quarter of the nineteenth century, and then continued with a detailed summary of modern physiology In this he dwelt but briefly on his own work, although he made a significant observation, as showing the continuity of his science that he had returned to the questions which agitated Harvey, and which had been left by Harvey for future inquiry

The "Principles of Human Physiology" made its appearance in 1915 This was a substantial and illuminating exposition solid in substance and individual in its lines of the state of physiology, by one who had added so much to the science Several editions have followed, the latest appearing in 1925, and as the work now stands it incorporates the advances made during the five years of war, and constitutes a comprehensive and suggestive treatise, valuable alike to advanced students and to practitioners

During the war Starling saw much service For the first two years after the outbreak of hostilities he was engaged as a medical officer with the Forces holding the rank of Captain, and at Milbank, as Colonel, he was in charge of the anti-gas department In 1916 he was appointed Chemical Adviser to the Salonika Forces, for which services he was appointed C M G, and the close of hostilities found him, after intensive work, on the Royal Society's Committee on Food Supplies, Scientific Adviser to the Ministry of Food In this position he was able to bring his extraordinary knowledge into the practical service of his country He kept before the public the need of continued scientific and statistical information while our present knowledge of many of the most important aspects of nutrition was so inadequate In those critical times he explained the relations of food and health to public efficiency, and the public obtained from him just views on the quality and quantity of food necessary for the maintenance of health, and proper instruction as to national and individual food requirements In the Oliver-Sharpey Lectures, delivered before the Royal College of Physicians, he summarised much of this teaching in a study entitled The Feeding of Nations, and he was then speaking as the British Delegate to the Inter-allied Food Commission For all this important national work Starling received no adequate recognition from the State

In 1923 he put the essence of his philosophy into the Harveian Oration, which he delivered before the Royal College of Physicians, under the title of The Wisdom of the Body Here a dissertation on the physiological laws of the heart and the powers and limits of adaptation was followed by an eloquent explanation of the chemical integration of the body. He closed with an insistence on the injunction of Harvey, to search out and study the secrets of Nature by way of experiment, thus hoping to attain to a comprehension of "the wisdom of the body and the understanding of the heart, and the mastery of disease and pain"

Starling, who is among Harvey's greatest descendants, was one of the last general exponents of experimental physiology, and the position was granted to him by the scientific world He served for several periods on the Council of the Royal Society, was a medallist of the Society and Vice-President in 1918–19 He received honorary degrees from Cambridge, where he had acted as an examiner, from Breslau, Strasburg, Sheffield, and Dublin, and was also Herter Lecturer in New York He spread essential truth for 30 years and more, to the benefit of mankind

His widow, who survives him, was a daughter of the late Sir Edward Sieveking, and he leaves by her three sons and one daughter He was buried at Halfway Tree, three miles from Kingston, on May 3rd, in the presence of the Governor and medical staff of the island

WILLIAM COLLINGRIDGE, M D, LL M, D P H CAMB

THE death of Dr W Collingridge, on April 29th, closes an eventful life which has proved of considerable service to the public, and especially to the City and Port of London, where he was for many years medical officer of health

Born at Islington in 1854, William Collingridge, who was the eldest son of William Hill Collingridge, who founded and edited the *City Press* He was educated at Clewer House, Windsor, and in 1875 went on to Christ's College, Cambridge In June of the following year war broke out between Serbia and Turkey, and

[1] THE LANCET, March 5th, 1927

Sir Berkeley Moynihan has been appointed a Deputy Lieutenant of the West Riding of the County of York

Irish Medical Association—The Council has nominated Dr H T Warnock, Donegal, to the Presidency of this Association and Mr P E Hayden, F R C S I to the Vice-Presidency Dr Warnock has been Vice-President for the past two years

Leigh Infirmary—Extensions of the Leigh Infirmary, Lancashire, and the new nurses' home were opened on April 30th The number of available beds will now be 70, and for the first time there will be a resident house surgeon

Yorkshire Refraction Hospital—The Lord Mayor of York, Alderman Oscar F Rowntree, has opened this hospital at Leeds, it is said to be only the second of its kind in the world It has been founded by the Yorkshire Optical Society, with the primary objects of training in hospital practice students taking up optical work and of providing spectacles for necessitous people Facilities are provided for extended practice in advanced refractive technique, with opportunities for clinical instruction and research, and there will be a voluntary staff

Shantung Christian University—Arrangements have been made for carrying on this University's work and that of the University Hospital now that the foreign staff has been compelled by consular order to withdraw from Tsinan The University is supported by 14 British, American, and Canadian societies and a Chinese executive committee has now been formed, including Dr P C Kiang (Associate Dean of the School of Medicine), who is a biochemist, and is hoping to begin research at Cambridge at the end of this year under Sir F G Hopkins The medical service of the hospital will be conducted by a group of Chinese doctors, graduates of the University School of Medicine The acting president of the University, Rev. J D MacRae, writes in warm terms of the helpful and friendly spirit which has been shown by all sections of the Chinese community

Far Eastern Association of Tropical Medicine The Government of India has invited the Far Eastern Association of Tropical Medicine to hold its seventh Congress in India in December next The Congress will open at Calcutta on Dec 5th, and scientific sessions will occupy the first week. The official delegates of the various countries will then visit other parts of India as guests of the Government The Congress and tour will end on Dec 22nd These dates are provisional Particulars of the Congress may be had from the General Organising Secretary, Lieut.-Colonel J Cunningham, I M S, Pasteur Institute, Kasauli, Punjab, British India.

Royal Institution—The annual meeting of the members of this institution was held on May 2nd, Sir Arthur Keith, treasurer and vice-president in the chair, when the annual report of the Committee of Visitors for 1926 was read and adopted The report of the Davy Faraday Research Laboratory Committee was also read, 64 new members were elected in 1926, and 78 lectures and 19 evening discourses were delivered The books and pamphlets presented amounted to about 229 volumes, making, with the 569 volumes purchased, a total of 798 volumes added to the library in the year The officers elected unanimously for the ensuing year were . President, the Duke of Northumberland, Treasurer, Sir Arthur Keith, Secretary, Sir Robert Robertson The Managers include Sir James Crichton-Browne, Dr J Mitchell Bruce, and Sir Almroth Wright

Care of Mental Defectives—Speaking at the post-graduate week of the College of Nursing, held at Manchester from April 25th to 30th, Dr W G Thomson deputy superintendent of the Cheadle Royal Asylum raised the question how far the liberties of mental defectives ought to be restricted Realising that in the majority of cases no cure but only an amelioration of the condition was possible, it remained to consider how this might be effected Much depended on the social and economic position of the parents The vast majority of defectives could not be cared for within the family circle At present the difficulty was that accommodation was insufficient for all the cases requiring treatment Even if this was surmounted there was always the argument that force must not be used, that the law must not be invoked to separate the kind parents from a member of the family who was the object possibly, of more affection than the normal children It did not appear wise to be too sentimental and such cases were more often happy in institutions than they were at home At institutions they received specialised attention and were kindly and humanely treated The real question at issue was whether the good of the child was to be subordinated to the liberty of the parents As to the problem of propagation he thought segregation was the remedy that appealed to most people

Dr Fawcett was re-elected a representative of the College on the Senate of the University of London —The death of the late Junior Standing Counsel to the College, Mr Dighton Pollock, was announced The President nominated Mr C Stafford Crossman, of Lincoln's Inn —The President announced that he had nominated, pending confirmation by the College, Dr C O Hawthorne, on behalf of the College, to serve on a Departmental Committee appointed by the Ministry of Health to consider a draft Bill prepared by the Joint Committee of Qualified Opticians to provide for the registration of optical practitioners and to regulate the practice of sight testing The nomination was confirmed —The Registrar reported that the President attended the reception of delegates to the Lister Centenary Celebration by the Prime Minister, at the British Medical Association's house on April 5th, as the representative of the College, and presented an address, and that the President, censors, and all the other College officers, with the exception of the treasurer who was out of England, attended the service at Westminster Abbey on the morning of April 6th —Dr H Morley Fletcher, the senior censor, was appointed a delegate to represent the College at the celebration of the centenary of University College, London, on June 23rd, 1927 —Dr R D Rudolf was appointed a delegate to represent the College at the celebration of the centenary of the granting of the Charter of King's College, Toronto, to be held on Oct 6th 1927, and two following days at Toronto —Dr S W. Wheaton was appointed a delegate to represent the College at the Third Imperial Social Hygiene Congress, to be held at the Caxton Hall, Westminster, from Oct 3rd to Oct 7th, 1927 —Dr C H Bond was appointed a delegate to represent the College at the commemoration of the centenary of the death of Pinel and the birth of Vulpian, to be held in Paris on May 30th and 31st, 1927 —A report was received from the committee appointed to make suitable arrangements for the celebration of the Harvey Tercentenary in 1928 It was decided that the celebration should have both a social and a scientific character The committee was empowered to proceed with these arrangements —The books and other donations presented to the library during the last quarter were received and the thanks of the College returned to the donors Special mention was made of a gift of six or seven very valuable books from Dr Herbert Spencer

After some further formal business, the President dissolved the Comitia

WEST KENT MEDICO-CHIRURGICAL SOCIETY —A meeting of this Society will be held at the Miller General Hospital, Greenwich on Friday, May 13th, at 8 15 P M, when Dr H Nockolds will deliver a presidential address entitled the Poor-law Hospital and its Relation to General Practice

UNIVERSITY OF LONDON —At recent examinations the following candidates were successful —

DIPLOMA IN PSYCHOLOGICAL MEDICINE.

With Special Knowledge of Psychiatry —Isaac Atkin G C Berg, Arthur Darlington, Florence M Gamble, P L Goitein, J F Williams

With Special Knowledge of Mental Deficiency —George Brown Mary V Littlejohn, Walter Wyatt

Medical Scholarships of the University of London Six medical entrance scholarships and exhibitions of an aggregate total value of £513, tenable at University College and in the medical schools of University College Hospital the London Hospital, and the London (R F H) School of Medicine for Women, are being offered The examination will begin on June 28th, and full particulars may be had from the Secretary of the Board, Mr S C Ranner, at the Medical School, King s College Hospital, Denmark Hill, London, S E 5

London Hospital Medical College (University of London) The Schorstein Memorial Lecture will be delivered by Prof Knud Faber, of the University of Copenhagen, on Thursday, May 19th, at 4 15 P M, in the anatomical theatre of the College The subject will be Gastritis its Relation to Achylia and Ulcer Members of the profession are invited to attend

London Hospital Dental School —A special lecture on Recent Medical and Dental Research on Accessory Food *Factors in Relation to Diseases of the Teeth will be given by* Dr J Sim Wallace on Monday, May 9th, at 5 P M in the anatomical theatre Members of the medical and dental profession are invited to attend

UNIVERSITY OF MANCHESTER —Dr J Webster Bride has been appointed lecturer, Dr K V Bailey assistant lecturer, and Dr J W A Hunter demonstrator in obstetrics and gynæcology Mr E E Hughes and Mr A H Southam have been appointed lecturers in operative surgery

UNIVERSITY OF BIRMINGHAM —The Ingleby Lectures will be delivered on May 11th and 18th, at 4 P.M, in the Medical Lecture Theatre (Edmund street Buildings), by Dr George F Still, on Place in Family as a Factor in Disease in Childhood Members of the medical profession are invited to attend

NATIONAL HOSPITAL FOR DISEASES OF THE HEART The "St Cyres" Lecture will be delivered by Dr J Strickland Goodall at this hospital on Tuesday, May 31st, at 5 P M The subject will be Some General Aspects of Myocarditis Tickets of admission from the Secretary at the hospital

The practice of the National Hospital for Diseases of the Heart is now open to students who have completed four years of medical study, and short courses of instruction in cardiology will be held immediately preceding the final examinations Particulars may be had from the Secretary

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION —On Wednesday, May 11th, Mr Sidney Boyd will give a special demonstration in surgery at the Hampstead General Hospital, and on the same date, at 12 noon, Mr Greeves will demonstrate at the Royal London Ophthalmic Hospital On Thursday, May 12th, at 1 30 P M, Sir Thomas Horder will give a demonstration at St Bartholomew's Hospital All members of the medical profession are invited to attend, without fee, these demonstrations arranged by the Fellowship Courses already in progress include one in urology at the All Saints' Hospital, one in psychological medicine at the Maudsley Hospital, and one in venereal diseases at the London Lock Hospital, whilst on Wednesdays a series of lecture-demonstrations on antenatal diagnosis and treatment is being given at the Royal Free Hospital by Prof Louise McIlroy The Central London Throat, Nose and Ear Hospital will hold an intensive course from May 9th to 28th, consisting of clinical and operative instruction The entry is limited, and early application is desirable The National Hospital, Queen-square, will give a course from May 9th to July 15th, consisting of clinical lectures and demonstrations, teaching in the out-patient department, besides a course in neurological anatomy and physiology, and one in methods of examination From May 16th to 28th the Infants Hospital will hold a course in diseases of infants, and the Hampstead General Hospital a course, especially for general practitioners (1 30 to 6 P M) in medicine, surgery, and the specialties The Fellowship can arrange practical courses in obstetrics and anæsthetics, and also make arrangements for clinical assistantships in gynæcology A general course of instruction is provided at the hospitals associated with the Fellowship Copies of all syllabuses and of the *Post Graduate Medical Journal* are obtainable from the Secretary of the Fellowship at 1, Wimpole-street, London, W 1

An Address

ON

FAILURES OF PROSTATECTOMY.

Delivered before the Manchester Surgical Society on March 22nd, 1927,

By Sir JOHN THOMSON-WALKER, M B Edin,
F.R C S Eng.,
SENIOR UROLOGIST AND LECTURER ON UROLOGY, KING'S COLLEGE HOSPITAL, SURGEON TO ST PETER'S HOSPITAL FOR STONE AND OTHER URINARY DISEASES

We have left behind the phase of prostatectomy where the mere fact of recovery from the operation is looked upon as a sufficient vindication of the skill and foresight of the surgeon, where the sole measure of success is the tally of the patients who leave the home or hospital alive That is, of course, the first criterion as to whether the operation is worth doing or not But having achieved a mortality figure that is low[1] considering the age of the patients operated upon (67 2 years), and the fact that the operation affects a vital organ and is a severe operation, we must be prepared to go a step further and inquire into the quality of the success which has followed the recovery from the operation

A patient who is left with a suprapubic fistula following the removal of a simple enlarged prostate is in a very much worse plight than if he had refused operation and resorted to catheter life A patient whose prostatectomy wound has healed but who has great difficulty in passing water and has to be relieved by catheter or must submit to repeated dilatations of the urethra is no better off for the operation He is, in fact, worse off for catheterisation before his operation was probably a simple matter, whereas after the operation it is extremely difficult A patient with a previously sterile urine who since his operation has suffered from cystitis, recurrent attacks of pyelitis, or of epididymitis, cannot be said to have improved his comfort or increased his prospect of life by having his prostate removed

These and some other types I should classify as failures of the operation of prostatectomy It is, I think, worth while considering how these failures come about and how they may be prevented or remedied, and this will be the subject of my remarks.

The causes of these failures may be reduced to two fundamental factors—namely, sepsis and obstruction

Sepsis. A Cause of Failure

I am afraid that there still lingers in the mind of many surgeons the idea that a urinary case is necessarily a septic case Sepsis in relation to enlarged prostate and prostatectomy is a failure of surgical methods and one that, I regret to say, appears to be widely accepted as inevitable.

I cannot agree with this view It is possible to catheterise a patient or to manage a catheter retained in the urethra over a long period and keep the urine aseptic It is possible to have the urine absolutely clear when the wound has closed after a prostatectomy I do not say that it is easy to produce this result; it is not But it is possible with extreme care in detail to achieve it in a large number of cases There are, of course, degrees in sepsis When I started urinary work every bladder wound in hospital was encrusted with phosphates, and the skin surrounding the wound inflamed and ulcerated by the alkaline decomposing urine This condition is not seen at the present day, but the urine in prostatectomy is almost invariably infected, and septic complications are very frequent The commoner septic complications are cystitis, epididymitis, seminal vesiculitis, pyelitis, and pyelonephritis

Infection may occur before the patient suffering from enlargement of the prostate comes to the surgeon, it may be introduced at the time of the operation, or it may occur subsequent to the operation when the cystotomy wound is still open. The number of cases of enlarged prostate that come to me with the bladder infected by the catheter is much smaller than it was 10 or 15 years ago, and is steadily diminishing, but they still amount to 44 per cent of private cases and 53 per cent of hospital cases

If the infection is moderate, and there is no evidence of pyelonephritis, a few weeks' preparation by thorough bladder-washing, either with intermittent catheterisation or with the retained catheter, together with diuresis and urinary antiseptics, will suffice as preparation for the operation Where a more severe grade of sepsis is present it will be necessary to perform suprapubic cystotomy and drain the bladder The immediate effect of cystotomy is a depression of the renal function and a consequent rise in the blood-urea If the patient recovers from this the question of removing the prostate will arise at a varying interval This is prostatectomy in two stages It is not possible to discuss the two-stage operation fully here, and I shall only deal with it in relation to sepsis

In all cases of severe urinary sepsis that do not clear up rapidly with bladder-washing, or appear unsuitable for this method, I drain the bladder by cystotomy for the treatment of the infection before performing prostatectomy The indwelling catheter provides insufficient drainage for a severe grade of cystitis A self-retaining catheter in the suprapubic wound is also inadequate, and a tube of sufficient size to allow of free escape of mucus and pus must be used Continuous irrigation through a catheter in the urethra and the suprapubic tube is the most effective method of treatment after the cystotomy

The number of cases in which this is necessary is small at the present day In 820 cases of prostatectomy performed up to the end of 1923, I performed a two-stage operation in 63, or 7 6 per cent In the last 200 private cases there have only been 5 in which the operation was a two-stage prostatectomy, and in all of these the cystotomy was done for severe sepsis In judging when these infected cases are fit for prostatectomy the urine and the general state of the patient may be sufficient But where the infection has spread to the kidneys and has not completely cleared up, it is desirable to obtain further information

The urea-concentration and blood-urea tests give information in regard to the renal function, and it may be assumed where these tests are satisfactory and the infection is moderate in degree that the prognosis for prostatectomy is good Where a severe grade of sepsis is present, the question of resistance of the patient to the infection is an additional factor in prognosis Recently MacAdam and Shiskin[2] have investigated the value of the cholesterol content of the blood as a measure of the resistance to infection possessed by the individual.

Cholesterol plays an undefined part in the process of immunity, stimulating, it is believed, the production of antibodies Immunisation processes have been shown to be accompanied by a high cholesterol content of the blood, a low "blood cholesterol" in a case of acute or chronic retention due to prostatic enlargement is significant of a low capacity for antibody formation, and points to the case being a bad operative risk as regards prostatectomy. The combination of a high blood-urea and a low cholesterol content is very serious Certain factors unconnected with renal suppuration, such as arterio-sclerosis, glycosuria, and malignant disease, produce a high blood cholesterol, and to some degree modify the value of this test

The normal average cholesterol content of the blood is 0 161 per cent Below 0 130 per cent is lectures daily —Maudsley Hospital, Denmark Hill, S E Special course in Psychological Medicine Further information from the Secretary

---

[1] The mortality in 156 consecutive private cases was 4 4 per cent The causes of death in 7 cases was pulmonary embolism 3 cases, acidosis 1 cerebral hæmorrhage four weeks after operation 1, diabetic coma 1, cerebral degeneration and circulatory failure 32 days after operation, 1

Births, Marriages, and Deaths.

BIRTHS.

Coope —On April 26th, the wife of G M Coope, M R.C.S, D P H, Queen's park, Manchester, of a daughter

Mann —On April 27th, at High West street, Dorchester, Dorset, the wife of E W Mann, of a son

Sneyd —On April 26th, at Harley street, the wife of George C Sneyd, F R C S I, of a daughter

MARRIAGES.

Carson—Honeywill —On April 20th, at St Barnabas, Addison road, Kensington, Dr Hugh Carson, of Selly Oak Hospital, Birmingham to Kathleen, youngest daughter of Mr William Honeywill, of 92, Oakwood Court Kensington (late of Adelaide South Australia)

Cole—Finlayson —On April 28th, at St Mary's Church, Chiddingfold, Surrey, Leslie Barrett Cole, M D, to Mary, younger daughter of Surg Captain H W Finlayson, D S O R N (retd)

Isbister—Henderson —On April 26th, at Edinburgh, Rollo Isbister, M B, Ch B, to Nita, youngest daughter of the late James Henderson, 31, Queen's crescent, Edinburgh

Perkins—Speedy —On April 30th, in Henry VII 's Chapel, Westminster Abbey, Alan Christopher Temple Perkins M C, M B B S, to Doris Macdonald Speedy, only daughter of Percy Speedy, Esq, A M I E E, of Lynton, Worcester Park, Surrey

Saward—Edwards —On April 28th, at the Parish Church, Ardingly, Sussex Arthur H M Saward, M R C S Eng, L R C P Lond, to Gavine elder daughter of the late Ernest William Edwards, Esq, of Heeleakah, Assam, and the late Mrs Gardiner, of The Old Court House, Richmond, Surrey

DEATHS

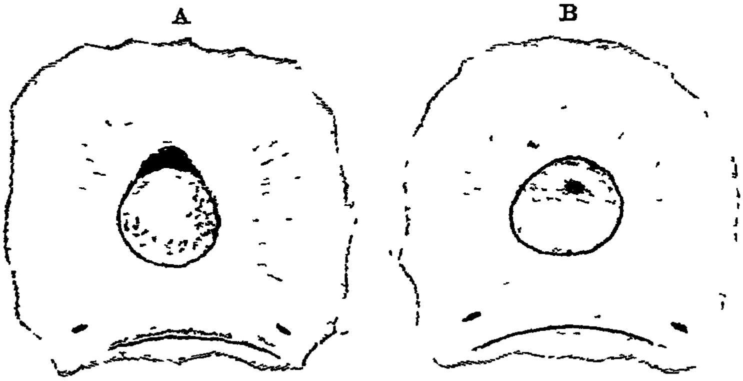
Batterbury —On May 2nd at Berkhamsted, Richard Legg Batterbury, M D, aged 83

Campbell —On April 23rd, at Shian, Woodcote road Wallington, suddenly, Patrick Edward Campbell, M B, C M Edin, in his 71st year

Smyth —On April 28th, at "Lota," Gerrards Cross, Bucks, William John Smyth, M D, late of Southport, aged 81

N.B —A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages, and Deaths silver nitrate solution The boric acid crystals re renewed every 12 hours If sepsis is already resent continuous irrigation is carried on by ttaching the tube of the reservoir to the catheter

FIG 2 —VARIETIES OF OBSTRUCTION AFTER PROSTATECTOMY



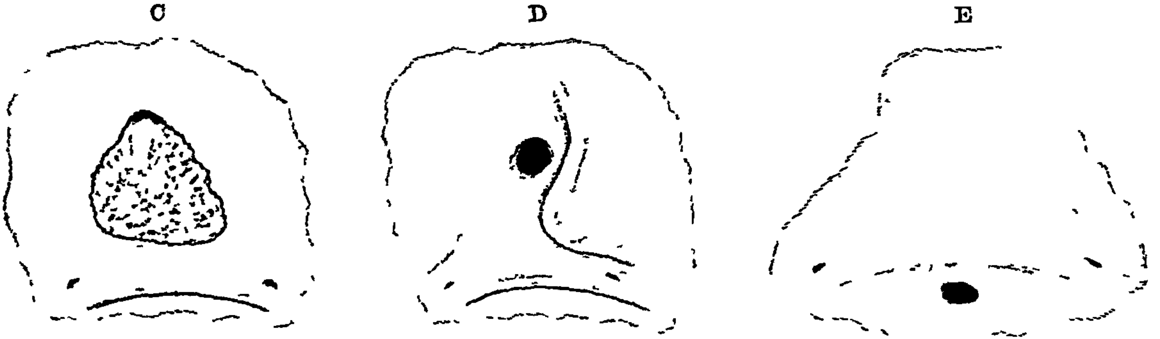
A = Nodule of prostatic tissue occluding internal meatus

B = Fibrous obstruction at lower part of prostatic bed

Epididymitis is the most frequent septic complicaion after prostatectomy, and the incidence of this omplication has been the subject of a number of rticles in the past ew years White[3] nvestigated 50 hospital cases and found the incidence was 82 per cent, and that in cases where there had been no previous infection the number amounted to 74 per cent, and in 33 per cent. the epididymitis was of a severe grade

As a remedy for post-prostatectomy epididymitis French surgeons have for some years performed bilateral vasectomy as a routine practice after removing the prostate gland and this has been adopted by some surgeons in this country I have no fundamental objection to the method of bilateral vasectomy after prostatectomy Many years ago I showed that the patient after prostatectomy is sexually sterile, although not impotent The section of the vasa is, therefore, a matter of no consequence so far as the procreative power is concerned But it appears to me to be a confession of failure on the part of the surgeon and, moreover, it is unnecessary

It is possible, by attention to detail in the prevention and treatment of sepsis in relation to prostatectomy, to avoid, with only rare exceptions, this complication In 140 consecutive private patients where my notes were sufficiently detailed as to leave no doubt as to the matter, there were 9 cases in which epididymitis was noted (6 4 per cent) In 5 of these cases the epididymitis was of a very mild grade amounting to local tenderness and slight thickening lasting a few days In 8 of the cases the urine had been infected before operation, and in one case there had been an attack of epididymitis before operation In 49 of the 140 cases the urine was infected before removal of the prostate, and no epididymitis followed the operation



C = Mass of granulation tissue occluding meatus

D = Contracted meatus with fold of mucous membrane

E = Complete occlusion of internal meatus with false opening behind trigone

In a very considerable proportion of my cases of prostatectomy, amounting to not less than 25 per cent, the urine was absolutely clear when the suprapubic wound healed up In the other cases, with a few exceptions, the urine was slightly cloudy, and in only a very few cases of pre-operation infection was the urine cloudy with a deposit of pus

Seminal vesiculitis is another septic complication of prostatectomy In cases of enlarged prostate, seriously infected before operation, it is one of the causes of persistence of urinary infection after drainage and energetic treatment of the sepsis has been carried out, or after the prostate has been removed In a few cases I have seen pus welling from the seminal vesical at the operation of prostatectomy, and I have laid the vesicle open into the bladder I have also found it necessary to remove the seminal vesicles in patients that have previously had the prostate removed, and suffer, after the operation, from persistent suppurative vesiculitis But this appears too serious an addition to the operation to carry it out at the time of the prostatectomy

OBSTRUCTION A CAUSE OF FAILURE

Obstruction after the operation of suprapubic prostatectomy for enlargement of the prostate varies from a slight difficulty in micturition to complete obstruction with suprapubic fistula

In 69 cases of severe obstruction following prostatectomy submitted to me for consultation, the conditions found were —

1 Fibrous contraction valvular folds or adenomatous nodules at the internal meatus or in the prostatic bed

2 New growth in the wall of the prostatic bed (*a*) Recurrence of simple enlargement of the prostate, (*b*) Malignant growth

I shall discuss these causes of obstruction

1 *Fibrous contraction at the seat of enucleation of the prostate*—In 1921 I published[4] 16 cases of obstruction due to the formation of the fibrous tissue in the area from which the prostate had been removed I have now seen 60 *cases of this condition* In all

---

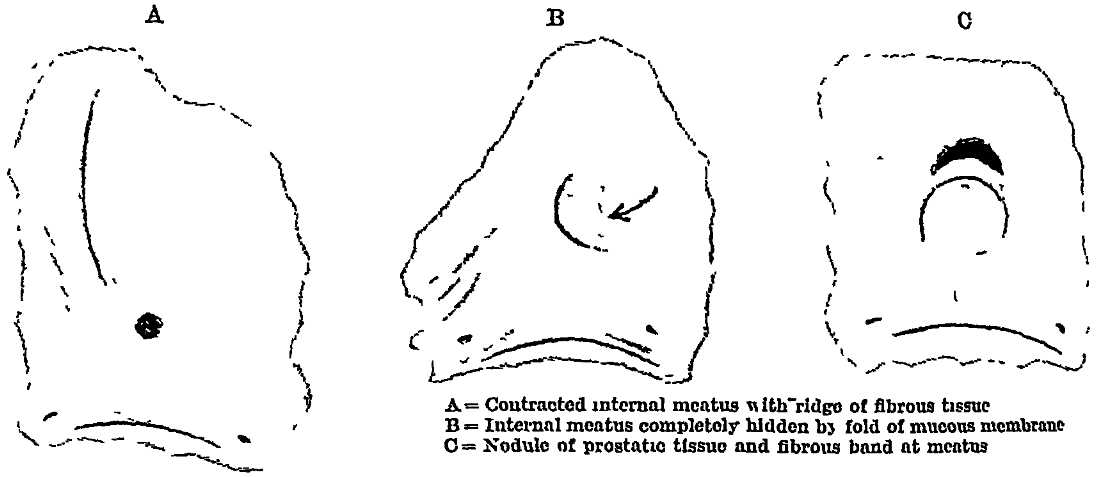
[4] THE LANCET, 1921, i, 1008

abnormal MacAdam and Sluskin found that of 18 cases with blood cholesterol less than 0 130 per cent 16 died of pyelonephritis and 2 recovered My own experience is at present confined to 23 cases In 6 of these, the blood cholesterol was below 0 130 per cent One calculous pyonephrosis died without operation, and the others made a rapid recovery after operation So far my cases have not been consistent, but the number is too small to draw any useful conclusions.

FIG. 1.—VARIETIES OF OBSTRUCTION AFTER PROSTATECTOMY.



A = Contracted internal meatus with ridge of fibrous tissue
B = Internal meatus completely hidden by fold of mucous membrane
C = Nodule of prostatic tissue and fibrous band at meatus

Sources of Sepsis

The causes of infection during and after the operation are numerous In the blind operation a small incision which will admit the first and second fingers is made in the abdominal wall and bladder In order to reach the prostate the abdominal wall must be forced down with the knuckles, and at the same time the forefinger of the left hand is introduced into the rectum and pushes up the prostate The left hand is necessary for the rest of the operation, so it is either regloved or hurriedly washed and used inside the bladder This proceeding is a source of infection of the bladder In many of these cases there is a considerable amount of kneading of the rectal wall by the rectal finger, a process likely to promote the passage of bacteria into the blood stream, whence they will reach the urinary tract

D = Contracted meatus and ridge of fibrous tissue

In order to avoid the rectal finger and the forcible pressure on the abdominal wall, I make an incision sufficiently long to allow the whole of the right hand to pass between the recti, the thumb remaining on the surface The enucleating finger can now work without strain at the enucleation of the gland It is difficult to understand why some surgeons fight shy of the extended incision It makes the operation much easier, reduces the time and effort of the enucleation, and thus reduces shock The wound, properly sutured, heals by first intention down to the tube, and is not the seat of hernia

The next source of sepsis is the tags, shreds, and partly detached nodules of prostatic gland, capsule, urethra and mucosa that are left after enucleation of the prostate when the blind operation is performed These shreds and nodules slough and form centres of sepsis, and a mass of slough encrusted with phosphates may be passed after the bladder has closed The dissection of these shreds and nodules is simply and quickly done by the open method, and is an important means of preventing sepsis The suprapubic tube used for drainage of the bladder does not adequately drain the prostatic cavity, and this cavity cannot be thoroughly washed out through it Examination of the first urine passed by the patient shows one or two drachms of pure pus which have been lying in the prostatic cavity.

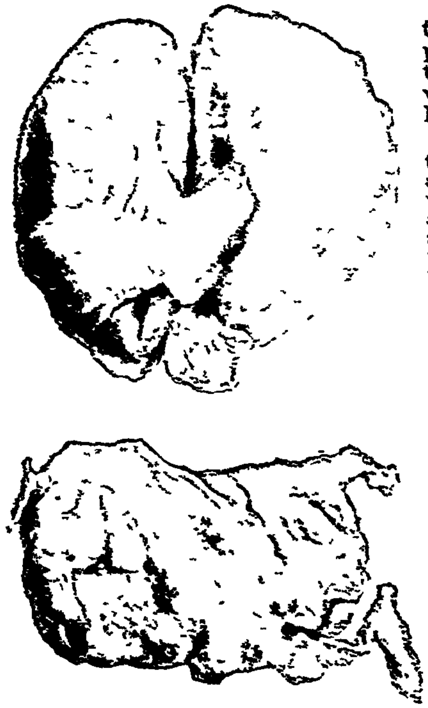
In order to wash out the prostatic cavity and prevent this accumulation, I tie a No 10 silk Coude catheter in the urethra, with the eye in the prostatic cavity Daily irrigation and, if necessary, constant irrigation, is made through the catheter and up through the suprapubic tube The catheter is removed on the seventh day, and at this time a considerable proportion of my cases commence to pass water, and in some the suprapubic wound is dry This indwelling catheter is used to prevent sepsis and epididymitis

The most common method of introducing sepsis after the operation is in the dressing of the suprapubic wound It is still a common method of treatment of the suprapubic wound to apply a dressing and voluminous layers of wool, and to change them after the dressings have become thoroughly soaked with urine It is impossible to avoid infection of the bladder when this method is used Urine is an excellent culture medium for bacteria, and the urine which soaks the dressings forms a direct communication between the skin of the abdominal wall, scrotum and perineum, and the bladder Drainage by a rubber tube or Paul's colostomy tubing attached to the suprapubic tube will keep the wound dry, but the interval between the removal of the tube and the closure of the wound allows infection to enter Immediate closure of the suprapubic wound and drainage by catheter in the urethra is too dangerous on account of hæmorrhage

The method I have found most successful is the Hamilton Irving suprapubic box This is fitted over the lower part of the wound, from which the tube projects Inside the box is placed a gauze bag of large boric acid crystals which practically fills the box The crystals are dissolved by the urine and form an antiseptic lotion The upper part of the wound which lies outside the box is protected with some antiseptic ointment Every day the box is removed, cleaned, and boiled, and the prostatic urethra and bladder are flushed with a large quantity

In 4 the transvesical operation had consisted in opening the bladder and making an attempt to dissect away the obstruction As far as I could judge these operations failed from not being sufficiently extensive to make a permanent cure

FIG 3



Enucleated prostate (above) and cuff of prostatic tissue dissected after enucleation

The operation that I performed on these 29 cases was as follows :—

1 All scar tissue in the abdominal wall was removed and the bladder separated from the abdominal wall

2 The bladder was dissected from the posterior aspect of the pubic bones and was completely mobilised

3 The fibrous ring was picked up in long forceps and cut backwards in the middle line and the scar tissue cut away round each side of the meatus, so that a free opening as large as the greatest expanse of the cavity was obtained. Where the meatus was obliterated a metal instrument was pushed up from the urethra and cut on from the bladder surface.

4 Dissection was if necessary carried into the prostatic bed, and layers of capsule and nodules of prostatic tissue removed.

5 The full Trendelenburg position good self-retaining retractors, a head light and long forceps and long curved scissors were required for this operation

6 If sepsis was present a catheter was tied in the urethra and constant irrigation carried out for several days

In all the 29 cases the operation was completely successful

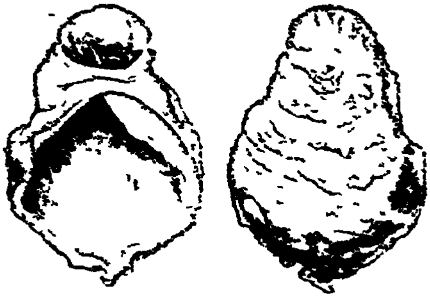
New Growth in the Wall of the Prostatic Bed

I shall now discuss certain changes in the wall of the cavity left after enucleation of a simple enlargement of the prostate

These are of two kinds: (*a*) recurrence of simple enlargement of the prostate, (*b*) malignant growth

Before discussing these cases I must refer for a minute to the anatomy of the enlarged prostate, and draw attention to two points that were familiar in the discussions that took place on the subject over 20 years ago

FIG 5



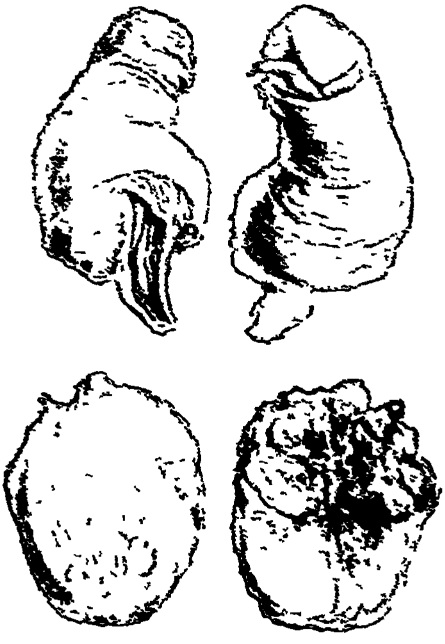
Anterior (left) and posterior (right) views of prostate removed at second prostatectomy

In simple enlargement of the prostate the changes take place for the most part in the neighbourhood of the urethra, and the outer part of the gland is expanded and compressed into fibromuscular layers between which remains of the flattened gland tissue can be seen These layers demonstrated by Cuthbert Wallace in 1903[6] form a thick capsule round the enlarged prostate In enucleating the prostate a varying thickness of this capsule is removed.

In 1904 I pointed out[7] that the portion of the prostate that was enlarged was situated above the ejaculatory ducts and that the verumontanum and ejaculatory ducts with the posterior walls of the prostatic urethra below this usually remain intact. The part of the prostate below the ducts remains behind after enucleation

In performing suprapubic prostatectomy it is sometimes possible to dissect out a cuff of fibromuscular tissue containing compressed gland tubules after enucleating an apparently perfect specimen of an enlarged prostate (Fig 3) This cuff lies at the upper and posterior part of the wall of the prostatic bed

FIG. 4.



Enucleated prostate apparently complete (above) with layer of malignant capsule dissected after enucleation

In these remains of the prostate that may be left behind after prostatectomy there are the nuclei from which further enlargement of the prostate may develop or malignant growth originate

The following instructive case recently came under my observation —

A. J B aged 64½ years, had suffered for some months from frequent micturition and dribbling The bladder was distended The prostate was enlarged, rather tough and somewhat fixed, and I noted that I considered it malignant although it was not actually hard or nodular

I operated in November, 1926 A round adenomatous nodule projected into the bladder and, to my surprise a well-formed enlarged prostate with two lobes and an intravesical lobe shelled out easily in one piece I was not satisfied, and examined the prostatic bed carefully and found a leathery capsule left behind This I dissected out as a cuff (Fig 4) Microscopical examination of the capsule showed that it was fibromuscular and showed gland alveoli It was infiltrated throughout with carcinoma The cancer cells were of small cuboidal type and arranged in alveolar masses sometimes showing a lumen Section of the prostate showed that at the outer part only it was infiltrated in places with cancer cells

Here the malignant growth had originated in the pathological capsule of a simple enlargement of the prostate and was spreading inwards towards the urethra these cases the blind operation described by Freyer had been performed It cannot be said that the post-operative obstruction in these cases was due to inexperience or lack of skill on the part of the operator Of the 60 cases, 37 were operated on by general surgeons attached to hospitals, 20 by urologists, and 3 by general practitioners practising surgery In all of these cases the degree of obstruction was severe In 26 there was a suprapubic fistula that had persisted since the operation or appeared shortly after the wound had closed In the other cases there was great difficulty in micturition There were recurrent attacks relieved with great difficulty by catheter in some cases Cystitis was present in most cases, but in a few the urine was clear In addition to this obstruction there were stones in the bladder in 6 cases, and stones in the prostate bed in 2

---

[6] THE LANCET, 1903 ii 1578

[7] Medico Chirurgical Transactions, 1904 lxxxvii, 403

The type of prostate present at the original operation might be expected to have an influence on the development of post-operative obstruction There was difficulty in discovering the type of prostate removed, but in 39 cases the condition was definitely stated It was small, fibrous, and difficult to enucleate in 17, adherent and containing calculi in 3, and large and easily enucleated in 19 The number of the two main types of prostate was therefore practically equal In all the cases the blind operation was performed and in 3 it was done in two stages

In most of the cases trouble commenced during the convalescence from the operation The passage of urine was delayed, the wound remained open for a prolonged period and then closed or it closed and broke down again, or it remained closed and difficulty in micturition developed Some patients passed no urine at all after the operation In cases where the wound healed completely or the fistula only discharged occasionally, the symptoms were those of severe obstruction with occasional periods of complete retention In such cases the patient was on catheter life, the catheter being passed with great difficulty

ANATOMY OF PROSTATECTOMY OBSTRUCTION

It is many years since I showed[5] that there are two danger points for the development of stricture after prostatectomy—namely, at the membranous urethra and at the outlet of the bladder where the mucous membrane is torn across It is rare to find any contraction at the membranous urethra In only 3 of the 69 cases was this the seat of obstruction The reason for this immunity from contraction is, I believe, the fact that the urethra is torn across obliquely, the tear extending from the level of the verumontanum posteriorly to the membranous urethra anteriorly The strip of mucous membrane that results from this oblique tear remains attached to the posterior wall of the prostatic bed This strip prevents the formation of a circular ring of fibrous tissue which might develop if the mucous membrane were torn transversely The point of narrowing in 59 out of 69 cases was at the prostatovesical opening In three of these there was obstruction at the membranous urethra and from fibrous tissue in the wall of the prostatic bed as well The nature and degree of the obstruction varied In 29 cases on which I operated there was fibrous contraction at the internal meatus in all cases There was in addition to this a great variety of folds and flaps of mucous membrane (Fig 1 B, C, Fig 2 D), nodules of prostatic tissue (Fig 1 C, Fig 2 A) or of granulation tissue (Fig 2 C), either overhanging the internal meatus or in the immediate neighbourhood of the outlet

In several there was a hard fibrous ridge passing backwards or laterally from the site of the internal meatus across the base of the bladder (Fig 1 A, D) The fibrous contraction formed a hard ring round the internal meatus, which was so narrowed as to admit a fine olivary bougie or a fine probe In 5 cases the internal meatus was completely obliterated and covered with mucous membrane so that no trace of it could be discovered In one of these cases a false passage had been tunnelled through the bladder base and opened into the bladder behind the trigone (Fig 2 E) in another a false urethra tunnelled through the right lateral wall of the bladder

Treatment of Post-prostatectomy Contraction

The treatment of the post-operative obstruction carried out by the surgeon who performed the prostatectomy was ascertained in 58 cases

In 5 cases there was no active treatment of the obstruction Dilatation by the passage of sounds was commenced during convalescence and carried out at intervals in 25 cases In 17 cases attempts to pass instruments failed In 11 cases a second operation was performed by the surgeon with the object of overcoming the obstruction In 7 of these the suprapubic fistula was enlarged the finger introduced into the bladder, and sounds passed through the internal meatus followed by a retained catheter In some of these cases the fistula healed, but the obstruction recurred in the rest the fistula persisted and the contraction at the internal meatus recurred

Treatment of post-prostatectomy obstruction of this nature may be transurethral by dilatation, with sounds or rupture with Kollman's dilator, cutting with Young's punch or a urethrotome, burning with high-frequency cautery, or by open operation

The choice between these methods must depend partly upon the degree of obstruction as estimated by the ease or difficulty with which instruments can be passed into the bladder In 18 of the 69 cases of post-prostatectomy obstruction (26 4 per cent) that came under my care, I dilated the stricture and treated the cystitis In 4 of these cases there were stones in the bladder, and after dilatation these were treated by litholapaxy These were cases where I was able to pass instruments without extreme difficulty and without causing a serious reaction

The point that struck me particularly about the cases where dilatation had already been carried out and failed was that the surgeon had either failed to realise the importance of sepsis in causing a relapse of the obstruction, or had been unable to cope with the infection In the less severe grades of obstruction I chose dilatation rather as an experimental method of treatment, for it had already been tried and failed I found that, when combined with very careful and thorough treatment of the sepsis and removal of stones when present, it was successful in this grade of obstruction, but that the patient required to be kept under observation in view of relapse of the sepsis or of the obstruction In the more severe grades where I used dilatation it was not from choice, but either because the patient refused open operation or his condition was such as not to justify so severe a method of treatment

In regard to treatment by cutting with the urethrotome, biting with Young's punch, burning with the high-frequency cautery, and bursting with Kollman's dilators, such methods are only applicable to the minor degrees of post-prostatectomy obstruction, for it is necessary that a large calibre instrument can be introduced through the contracted internal meatus I personally prefer intermittent dilatation, combined with the retained catheter and thorough treatment of sepsis for this grade of obstruction

In the more severe grades of obstruction these methods do not come into consideration, for the necessary instruments cannot be introduced into the bladder

Operation for Post-prostatectomy Obstruction.

In 40 cases of obstruction after prostatectomy that were submitted to me, I recommended operation (57 9 per cent), and in 29 of these I operated for the obstruction The treatment previous to my examination in the 29 cases had been as follows —

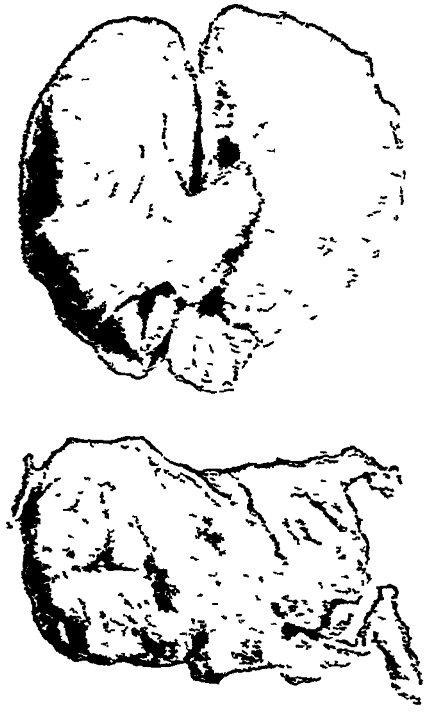
Dilatation	15
Attempted dilatation that failed	5
Transvesical operation	9

---

[5] Brit Med Jour, 1905, ii, 1250

In 4 the transvesical operation had consisted in opening the bladder and making an attempt to dissect away the obstruction. As far as I could judge, these operations failed from not being sufficiently extensive to make a permanent cure.

FIG. 3.



Enucleated prostate (above) and cuff of prostatic tissue dissected after enucleation.

The operation that I performed on these 29 cases was as follows:—

1 All scar tissue in the abdominal wall was removed and the bladder separated from the abdominal wall.

2 The bladder was dissected from the posterior aspect of the pubic bones and was completely mobilised.

3 The fibrous ring was picked up in long forceps and cut backwards in the middle line and the scar tissue cut away round each side of the meatus, so that a free opening as large as the greatest expanse of the cavity was obtained. Where the meatus was obliterated a metal instrument was pushed up from the urethra and cut on from the bladder surface.

4 Dissection was if necessary carried into the prostatic bed, and layers of capsule and nodules of prostatic tissue removed.

5 The full Trendelenburg position good self-retaining retractors, a head light and long forceps and long curved scissors were required for this operation.

6 If sepsis was present a catheter was tied in the urethra and constant irrigation carried out for several days.

In all the 29 cases the operation was completely successful

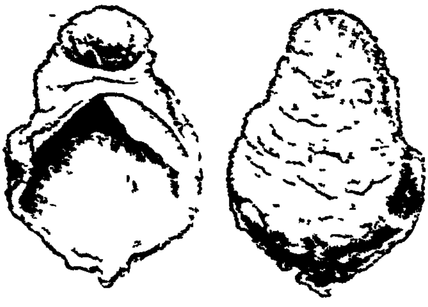
New Growth in the Wall of the Prostatic Bed

I shall now discuss certain changes in the wall of the cavity left after enucleation of a simple enlargement of the prostate

These are of two kinds: (*a*) recurrence of simple enlargement of the prostate (*b*) malignant growth

Before discussing these cases I must refer for a minute to the anatomy of the enlarged prostate, and draw attention to two points that were familiar in the discussions that took place on the subject over 20 years ago

FIG 5

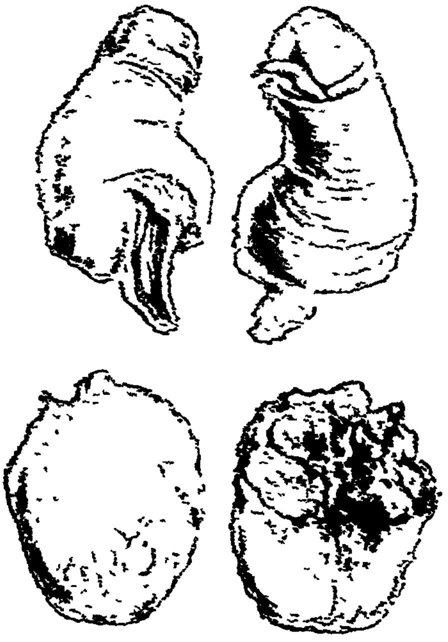


Anterior (left) and posterior (right) views of prostate removed at second prostatectomy

In simple enlargement of the prostate the changes take place for the most part in the neighbourhood of the urethra, and the outer part of the gland is expanded and compressed into fibromuscular layers between which remains of the flattened gland tissue can be seen These layers demonstrated by Cuthbert Wallace in 1903[4] form a thick capsule round the enlarged prostate In enucleating the prostate a varying thickness of this capsule is removed.

In 1904 I pointed out[5] that the portion of the prostate that was enlarged was situated above the ejaculatory ducts and that the verumontanum and ejaculatory ducts with the posterior walls of the prostatic urethra below this usually remain intact. The part of the prostate below the ducts remains behind after enucleation.

FIG. 4.



Enucleated prostate apparently complete (above) with layer of malignant capsule dissected after enucleation.

In performing suprapubic prostatectomy it is sometimes possible to dissect out a cuff of fibromuscular tissue containing compressed gland tubules after enucleating an apparently perfect specimen of an enlarged prostate (Fig 3). This cuff lies at the upper and posterior part of the wall of the prostatic bed.

In *these remains of the prostate that may* be left behind after prostatectomy there are the nuclei from which further enlargement of the prostate may develop or malignant growth originate.

The following instructive case recently came under my observation:—

A. J. B., aged 64½ years, had suffered for some months from frequent micturition and dribbling The bladder was distended The prostate was enlarged, rather tough, and somewhat fixed, and I noted that I considered it malignant although it was not actually hard or nodular.

I operated in November, 1926. A round adenomatous nodule projected into the bladder and to my surprise a well-formed enlarged prostate with two lobes and an intravesical lobe shelled out easily in one piece I was not satisfied, and examined the prostatic bed carefully and found a leathery capsule left behind. This I dissected out as a cuff (Fig. 4) Microscopical examination of the capsule showed that it was fibromuscular and showed gland alveoli It was infiltrated throughout with carcinoma. The cancer cells were of small cuboidal type and arranged in alveolar masses sometimes showing a lumen. Section of the prostate showed that at the outer part only it was infiltrated in places with cancer cells.

Here the malignant growth had originated in the pathological capsule of a simple enlargement of the prostate and was spreading inwards towards the urethra.

---

[4] THE LANCET 1903 ii 1578

[5] Medico-Chirurgical Transactions 1904 lxxxvii., 403

It is not possible here to discuss the whole question of the development of malignant growth in a simple enlargement of the prostate This case illustrates one type of this form of growth

I have met with a number of cases where the prostate had been removed, and it was stated that the gland had shelled out easily, and after an interval of one or several years obstruction recurred On examination, there was a malignant infiltration of the upper part of the wall of the prostatic bed. These cases are, I think, similar to that I have just described

Recurrence of the Simple Enlarged Prostate

Incomplete removal of the enlarged prostate when only the intravesical projection of the prostate is removed or where only one lobe has been enucleated is occasionally met with and is easily recognised In these cases the patient is free from symptoms for a period and obstruction again develops These cases require no further discussion

A more important form of redevelopment of prostatic obstruction occurs when the enlarged prostate is reconstructed after what apparently was a complete enucleation The following is such a case :—

J C , aged 77, consulted me in 1916 on account of recurrent retention of urine The prostate was much enlarged, elastic, and movable I operated in May, 1916, and removed a large bilobed adenomatous prostate He was well for nearly ten years, and then began to have difficulty and frequency of micturition which increased rapidly for three months On rectal examination the prostate felt enlarged and similar to an ordinary enlargement of the prostate of moderate size In August, 1926, I opened the bladder and found an adenomatous nodule projecting at the internal meatus Partly by enucleation with the finger and partly by dissection I removed the nodule together with a complete ring of prostatic tissue After removal the specimen resembled, from the posterior aspect, an ordinary enlargement of the prostate with an intravesical lobe (Fig 5) From the anterior aspect the ring was complete only at the upper part, below this was an open trumpet-like tube with a smooth lining on the surface of which small openings of gland ducts could be detected

Microscopical examination showed a fibromuscular stroma with prostatic gland acini of various sizes similar in appearance to an ordinary adenomatous prostate

I have examined in consultation a number of cases where the prostate appears to have been reconstructed in similar fashion after enucleation of a complete specimen of enlarged prostate The recurrent simple prostate undoubtedly takes origin in layers of the pathological capsule that have remained in the wall of the prostatic bed A thick layer of this capsule is sometimes seen at the open operation and may be dissected without difficulty

Time of Healing.

I have discussed the two chief causes that delay healing and give rise to a persistent suprapubic fistula I will, in closing, refer more particularly to the time of healing of the suprapubic wound It is, I am afraid, a state of perfection at present unattainable that the bladder should be completely closed by suture at the end of the operation of suprapubic prostatectomy If this could be accomplished the danger of post-operative infection would be reduced to a minimum or entirely abolished

Two important factors prevent the adoption of this method—namely, pre-operative infection and hæmorrhage I look forward to the time when all operations on the prostate will be performed in an aseptic urinary tract and this objection would be eliminated The danger of hæmorrhage in a closed bladder would, however, remain

We must for the present therefore, accept the necessity for draining the bladder until the danger of reactionary hæmorrhage is passed and, if the urine is already infected, until the infection has been cleared up or granulation established in the raw prostatic bed It is another matter when this drainage becomes prolonged into a fistula

In an excellent article on the closure of the suprapubic urinary fistula following prostatectomy, Winsbury White [8] records observations on 68 hospital cases In these cases the average time in which micturition commenced was the nineteenth day In 60 per cent spontaneous micturition commenced on the twenty-first day. In 25 per cent micturition was delayed until the fourth week The earliest time of removal of the suprapubic drainage-tube was the seventh day The cases in which the drainage-tube was retained until the tenth day had less temperature and healed more quickly, the average time of closure of the fistula being the twenty-first day as compared with the twenty-eighth day, when the tube was removed on the seventh day Freyer held that patients who passed urine early in the convalescence often did badly

I have collected the dates in regard to 200 of my own private cases where the operation and after-treatment was uniform In all these cases a catheter was tied in the urethra, with the eye in the prostatic cavity at the time of the operation, and was retained for 7 days A Hamilton Irving box was applied soon after the operation, and daily or constant continuous irrigation was made through the catheter The tubes were removed on the fourth day and the catheter on the seventh day. The Hamilton Irving box was used until the wound was dry

I have omitted from these figures 3 cases which were so unusual as to depart altogether from the routine of my practice Two were cases of very severe sepsis where the bladder had been drained elsewhere, and I only did the second stage of the operation The other patient was very ill with chronic retention and sepsis, and there was a prolonged interval between the two operations and a tedious convalescence These 3 cases could not be regarded as representing the usual post-operative course With these exceptions the cases are consecutive and the results for three years are as follows —

		Day average		Day average
1924	Urine passed	13 1	Wound dry	16 7
1925	,, ,,	12 1	,, ,,	16 4
1926	,, ,,	10 1	,, ,,	16·0

In 1926, but for one or two long cases, the average day on which the wound was dry would have been better, as is shown in the following percentages —

In 1924	48 4	per cent were dry on or before the 15th day
,, 1925	44 4	
,, 1926	57 1	

Several patients passed urine when the catheter was removed on the seventh day, and were dry from that time

---

Donations and Bequests —Under the will of the late Mr Arthur William Scott, of St David's College Lampeter, Cardiganshire, the testator left, among other bequests, £7000 to the University of Cambridge, the income to be applied for the furtherance of physical science in such manner as the authorities may determine, £1000 to the Royal Society, the income to be applied for the advancement of the physical sciences as the president and council shall determine, £1000 to King Edward's Hospital Fund for London, £500 to the Royal National Lifeboat Institution The residue of the property as to one-third to the University of Cambridge, the income therefrom to be applied for the furtherance of physical science, one-third to the University of Oxford for like purposes, and one-third to St Thomas's Hospital London —Mr Henry Swain Bennett, of Holmewood, Kirby Muxloe, Leicestershire, who left £149,911, directed that after certain provisions the remainder of his property is to be divided between the Leicester Royal Infirmary and the Leicester, Leicestershire, and Rutland College, then on the death of a beneficiary he gives £5000 to the said college, £5000 to the Leicester Royal Infirmary, and certain other bequests, including £500 each to the Leicester Guild of Cripples Leicester and Leicestershire Maternity Hospital, Leicester Charity Organisation Society, Leicester District Nursing Association the Institution for the Blind, and the Leamington Home for Incurables —Mr Douglas Douglas Crawford, F R C S , of Rodney-street, Liverpool, bequeathed £1000 to the Liverpool Royal Southern Hospital after his wife's death

A NOTE ON THE PREPARATION AND PROPERTIES OF THE
OVARIAN HORMONE IN A WATER-SOLUBLE FORM

By F. DICKENS, M.A. Camb., Ph.D.,
E. C. DODDS, M.D., Ph.D., M.R.C.P. Lond.,
and
D. J. TRESCOTT BRINKWORTH, A.I.C., A.C.G.F.C.
(*From the Biochemical Department, Middlesex Hospital.*)

Up to the present time the ovarian hormone has in the main only been obtained in the form of an oil insoluble in water, but soluble in organic solvents such as acetone, ether, and alcohol.

The original preparations of Herrmann and Frankel[1] and those of Allen, Doisy, and their co-workers[2] have been completely insoluble in water. In a communication from these laboratories (Dickens, Dodds, and Wright[3]) the work of these observers was repeated, confirmed, and extended, and since that time various clinical trials of material obtained by these processes have been made. A great difficulty has, however, been experienced owing to the fact that the material can only be administered either in the form of an oily solution or as an emulsion in some solution such as dilute aqueous sodium bicarbonate. If the former be employed it is found that prolonged administration in large doses often leads to the development of hard, painful nodes under the skin, and also the absorption of the material is very slow.

The second type of preparation—namely, bicarbonate emulsion—is unsuitable for general clinical work owing to the fact that the material tends to settle out in a coagulated form, with the result that even prolonged shaking does not succeed in producing a uniform emulsion.

It was felt, therefore, that before any extensive clinical trials could be made with this material, the method of extraction would have to be so modified as to yield a product which would either be soluble in water or which would be absorbed much more readily than the older one referred to above.

There have been many attempts in the past to prepare this œstrus-producing hormone in a water-soluble form, and amongst the most prominent of the published names are those of Zondek and Aschheim,[4] and of Laqueur, de Jongh, Hart, and Wijsenbeek.[5] In our hands, however, these methods have proved to be unsatisfactory, and on repeating the experiments of these authors we have not succeeded in obtaining the hormone in a water-soluble form. The oily material of the original process of Herrmann and Fränkel was treated in a variety of ways in the hope of rendering the active portion soluble in water. Thus mild acid and alkaline hydrolysis were tried without success, and even saponification with sodium ethoxide in an atmosphere of nitrogen was found to destroy the potency slowly without liberating any active water-soluble material.

It appeared, therefore, that some entirely new method of extraction would have to be evolved before the desired result could be effected.

During the course of this work some experiments which had been performed in these laboratories on an entirely different subject yielded some very valuable suggestions. A series of extractions of the suprarenal gland was being performed in the hope of obtaining a substance that would benefit cases of Addison's disease. In one investigation a quantity of suprarenal glands was extracted with alcohol in the manner described by Herrmann and Fränkel and Allen and Doisy for the preparation of the ovarian hormone. In fact this technique was followed in closest detail, and the final product was a clear oil completely soluble in ether, acetone, alcohol, and other organic solvents. The product was exactly similar to ovarian hormone in physical properties. Bicarbonate emulsions of this material were found to be very strongly pressor in action when injected into cats arranged in the usual manner for recording blood pressure upon a kymograph, and it was subsequently found that this effect was due to adrenalin held in solution in this oily material. It was naturally very surprising to find adrenalin present in a mixture which was completely soluble in ether, and one was tempted to think that if the original investigators had used this method of extraction instead of an aqueous one it would have been quite possible that this substance might have been regarded as being of a fatty nature, as many workers have regarded the ovarian hormone. We therefore decided to employ an entirely new method of extraction, and the first one tried was the acetone picric acid process which has been used by us for the preparation of insulin (Dodds and Dickens[6]). We obtained from ovaries by this process a small quantity of water-soluble hydrochloride which produced œstrus when injected into castrated animals. The method of extraction was complicated by the fatty nature of the tissue, and for subsequent experiments we employed placentas exclusively.

Details of Experiments.

The following experimental details show that it is possible to obtain by the acetone picric acid process, and by modifications of it, the ovarian hormone in the form of a water-soluble hydrochloride. The yields obtained by this process, however, were very small, as will be seen from the experiment quoted below.

Minced pigs' ovaries were mixed with dry picric acid and extracted with 70 per cent. acetone. The acetone was removed by vacuum distillation, and the dry picrate obtained on filtering the aqueous residue was extracted with acid alcohol. On adding 15 volumes of acetone to this extract a precipitate formed, which, when well washed with ether and dried in vacuo, proved to be very soluble in water and to produce œstrus in ovariectomised rats in doses of 10 mg. The yields obtained by this method were of the order of 40 rat units per kg. On applying the above method to placenta, yields of over 90 units per kg. were obtained, the weight of one rat unit being 4.5 mg.

A long series of experiments was then conducted on the acid extraction of placenta. A typical experiment may be quoted as follows. 1400 g. of finely minced placenta were mixed with an equal weight of 7 per cent. hydrochloric acid and heated on a steam bath for five hours with frequent agitation. The pH was then adjusted to 3 and the mixture passed through a Sharple's centrifuge. On adding an equal volume of saturated aqueous picric acid a heavy precipitate was obtained which was filtered off on a Buchner funnel and extracted with acid alcohol (absolute alcohol 75 per cent., 3 N HCl 25 per cent.). The extract was treated with 15 volumes of acetone and the hydrochloride thus obtained well washed with ether and dried in vacuo. The yield in this experiment was 6.11 g., and this was found to be strongly active in 2.5 mg. doses (=1000 rat units per kg.).

Subsequent experiments show that still larger yields may be obtained by variation of the hydrogen-ion concentration to which the extract is adjusted before filtration. Active material may also be obtained by iso-electric precipitation. These points are under investigation.

The product so obtained is a pure white powder very soluble in water. It can be boiled in aqueous solution for a considerable period without loss of activity. The active principle passes completely through a collodion membrane, and the substance may be purified to some extent by this means. On extracting material active in 5 mg. doses with hot butyl alcohol the filtered extract yields a product the rat unit of which is 0.5 mg.

The chemical constitution is being investigated. The substance appears to be relatively simple and contains a fairly large proportion of sulphur. The

Pauly reaction for histidine is strongly positive Tryptophane also appears to be present

Standardisation of the products described above was carried out upon young rats of uniform weight they were ovariectomised and swabs were taken daily for seven days, or until seven consecutive smears typical of di-œstrus were obtained The animals were then divided into batches of six and varying doses were given to each batch The unit was taken as the smallest dose producing cornification within 48 hours in a batch of six rats This work was carried out by Dr J Lee Warner, who also introduced an additional check by mating the injected females and noticing the presence of vaginal plugs He was successful in obtaining plugs with this new water-soluble material, but found that a greater dose was required to produce mating than to evoke œstrus This problem will be the subject of a separate communication

Summary

A method is described for obtaining the œstrus-producing hormone in a water-soluble form by extraction from placenta, the yield being over 1000 rat units per kg The activity of the preparation can be easily reduced to below 0 5 mg per rat unit Further work indicates that this degree of purity may be exceeded without much difficulty The properties of the new extract are discussed

THE PSYCHOLOGICAL TREATMENT OF MANIA AND DEPRESSION.

BY ERNEST SNOWDEN, M B, B S LOND,

PSYCHOLOGIST TO THE HOSPITAL FOR EPILEPSY, MAIDA VALE, AND ASSISTANT IN THE DEPARTMENT OF PSYCHOLOGICAL MEDICINE, ST BARTHOLOMEW'S HOSPITAL

OF late years the treatment of certain cases of mental disorder without certification has become a practice amongst psychologists and the more advanced medical practitioners Cases of mental disturbance which would have been certified without hesitation only a few years ago are now recognised as being capable of treatment in their own homes or in an ordinary nursing home

The advantage of this to the patient is very great, so great that the physician is justified in taking a certain amount of risk in following this line of treatment so long as he is doing so with the cooperation of the patient's relatives It is important to realise that a patient need not of necessity be certified because he is certifiable

It is a fact that a great many cases of insanity can be prevented if they can be properly dealt with before the condition has completely developed Certification is a very serious matter for anyone The time will, no doubt, arrive when treatment in an asylum will lose the terror that is at present attached to it, but certification now means to the ordinary individual the giving up of the struggle, that from fighting his condition he is reduced to helplessness, that he has reached the lowest levels of mental capacity, and that his failure to overcome his illness is complete From this state the re-education process is slow and difficult, and the fact of certification leaves behind it a feeling of insecurity which must take many years for its removal, if indeed it ever disappears

To the ordinary individual the segregation of the insane patient is so absolute, he is cut off from his fellow men, and his life as a member of his community ceases It is for this reason that the lot of anyone recently discharged from an asylum is so hard He is returning to live in a tribe which has once turned him out Before he is readmitted to the life of the tribe everyone around him must be convinced that the condition which made his exclusion necessary will not return This state of affairs renders his return to ordinary circumstances more difficult, and produces in him a state of apprehension inimical to recovery It is the intention of this paper to consider two of the milder forms of psychosis and to show how these may be foreseen and prevented

The emotional states such as fear, sex, and anger are preparations for physical activity The natural result of the presence of something dangerous in our environment is that we should run away, and the condition that we recognise as fear is a preparation in the body to enable that escape to be effected Similarly, anything that threatens to injure some person or thing that we would naturally protect arouses us to a condition of body which we recognise in ourselves as anger These emotional states are, therefore, physical, and they are permitted a certain amount of expression in a civilised community, although they are not allowed to attain complete satisfaction Rage, for example, is discouraged and punished because of its danger to others, while anger, which is a controlled rage, is tolerated

Physical exercise assists in providing an outlet for the forbidden activity, while relief can sometimes be obtained by substituting one emotion for another For example, a soldier in the trenches who is afraid of the shells that threaten him and who cannot run away can attain some degree of relief by the physical activity of digging, or if this is denied him, by shouting or using bad language, or by some expression of anger In this last case an emotion (panic) which is not allowed by civilisation is expressed through the channel of an emotion (anger), of which civilisation is tolerant In this example it will be seen that there is something to express which needs an actual physical activity to express it

These activities are, for the most part, concerned with the motor functions of the body The digestive functions, and those functions which are associated with digestion, are left unstimulated and tend to stop, so that a stasis of the intestine occurs and a lowering of the activity of the liver These two changes have been mentioned as examples and to indicate the nature of the physical disturbance which is occurring If these changes happen frequently, the result will be an habitual stasis of the intestine, an increase of the dangerous intestinal flora, and an absorption of toxins which will increase the depression and so give rise to a vicious circle The commonest emotion and the one most likely, apart from the frequency of its occurrence, to bring about this state of affairs will be the emotion of fear It must be remembered that fear may be aroused by actual danger, by the recall of a terrifying memory, either consciously or in the form of a phobia, or by a purely imaginative process in which the patient pictures himself or someone belonging to him in a position of danger.

It will presently be shown that the two conditions of depression and excitement are closely allied The chief difference between them seems to be that the depression state is the result of failure to secure any outlet for the physical activity which results from an emotional response, while the state of restlessness is an expression of that activity, not necessarily directed towards the object for which it was aroused, but possibly spread over all the events of the patient's life The cause of the condition is the same in both cases, being the control that is exercised by civilisation in preventing the expression of natural desires This control has also this effect, that it prevents the recognition by the patient in a great number of these cases of the actual desire which is being stimulated, and so denies to him the opportunity of dealing with the difficulty for himself in a logical manner.

Mania

Where the conditions of the patient's life are such as to produce a constant stimulus of one or other of these emotions there will result an activity in excess of the normal needs of the individual and the consequent development of restlessness, excitability, and mania

Restlessness is an extremely common symptom in conditions of anxiety, and it is very frequently present in states of depression Patients rarely complain of this symptom alone, but the fact that it exists is evidence of the presence of a stimulus of some kind strong enough to arouse activity in the motor mechanism A characteristic of it is that it leads the patient to expend more physical energy in the carrying out of any activity than the task demands or than would be needed by others for its performance Excitability is only a further degree of the same condition, except that the energy is always present, ready to be fired off at the slightest stimulus, and usually resulting in an expression of anger in circumstances where the ordinary healthy individual would exercise control, anger being, as stated above, the emotional activity of which civilisation is most tolerant Mania is a condition in which control is largely in abeyance In this condition the violence is expressed without any apparent outside stimulus whatever, and is often directed aimlessly upon animate or inanimate objects indiscriminately It will be of value to consider the bodily mechanism which underlies all this activity

In considering the activity of the excitement state we must realise that, apart from those functions which are directly or indirectly concerned with digestion or excretion, the whole body is involved, and it is obvious that there must be some mechanism at work more potent than that which is ordinarily employed in everyday life The activity is so persistent, so untiring, and in the acute condition of mania so violent, that it may go on to complete exhaustion and death This degree of activity could only be attained for a very short space of time if conscious effort were the only stimulus being employed It appears that the glands of internal secretion play a large part in this mechanism, and that the gland which is chiefly concerned is the parathyroid This gland is said to be stimulated by the products of muscular activity circulating in the blood stream The parathyroid secretion produces an over-excitability in the brain-cells leading to a greater activity or preparedness for activity in the motor cortex This in turn produces a condition for which muscular activity is the only relief, and leads to the development of a vicious circle

Some such cycle as this would account for the restlessness in people who feel that they must constantly be doing something without pause, resting only when they are asleep, and achieving the state of sleep only with difficulty This mechanism would account also for the phenomenon which has been observed by everybody—namely, the occurrence of sleeplessness at the end of a day when the muscles have been used more than usual and when the individual himself is actually very tired In the excitement state sleeplessness is a very common symptom, and the distress caused even in the milder forms of this condition by the experience of night after night of wakefulness is very great, and is one of the most important of the symptoms against which treatment must be directed In such cases rest in bed must be enforced until the vicious circle is broken, and the best sleeping draughts are those which act as depressants to the activity of the motor cortex

The following case illustrates the condition which has just been described

A man, aged 35, manager of a large factory, complained of restlessness with attacks of extreme excitability, amounting at times almost to maniacal outbursts These were largely directed against his wife of whom he was very fond He was restless at the office, making work for himself when he might have remained unoccupied, he was restless in his amusements, only enjoying golf or bridge if there were high stakes to make the game exciting Between two rounds of golf he would hardly wait to finish his lunch before he was worrying his friends to start out again He slept poorly The condition threatened his home life and made him acutely miserable He realised that these outbursts of excitement were unreasonable, and yet he was unable to prevent them, so that he was frequently morose and depressed He believed that he would become insane and he feared that he might injure his wife in one of these excitement states

His family history was of importance His mother had deserted his father when the patient was only 5 years old, and the patient and his brother had been brought up by foster parents who were not particularly kind to them At the age of 14 the only kindness that the patient had received had been from his father's solicitor, who managed their affairs, and from this man's wife His father, who was an invalid, played a very small part in the patient's life and he saw him very little

The patient went to school in Ireland and was a keen Rugby football player At the age of 19 he believed himself to be in love with his guardian's sister who was 14 years his senior At that age he went to South America, where he was extraordinarily successful, and at the age of 23 he returned to England to join the army. He had considerable experience as an infantry officer, and then transferred to the R A F, where he took a pilot's certificate He then developed attacks of asthma and was eventually invalided out of the army When he was 26 he married his guardian's sister who was then 40 years old He realised that it was taking a definite risk for anyone of his age to marry someone so much his senior, but he felt compelled to take the step Soon after this he obtained his present employment as manager of some works abroad, where he was brilliantly successful

He found that his wife, who had achieved considerable social popularity in the place where she lived, was one of those people whose chief object in life is to be a social success, and he conceived the idea that she was neglecting him in order to please other people This habit of hers was a constant source of grievance to him, and was the invariable cause of their quarrels She was quite unable to change her life-long habit, while he began to see neglect of himself in her most trivial actions He was obsessed with the idea that she must think of him first in everything, in fact, he behaved just as a spoilt child would do

The examination of his mind made it clear that he was looking upon his wife as if she were his mother and demanding of her a complete absorption in his affairs This attention she was either unable or unwilling to give, with the result that the patient developed the excitement symptom which was a manifestation of the energy which he might have used in primitive circumstances to insist upon her compliance with his wishes, but which his civilised mind endeavoured to keep under control This energy was expressed in the excitement condition in which he lived, his energy begetting more energy in the manner that has been described above

The *treatment* can be briefly described He was put to bed in a nursing home and given sedative drugs, with the idea of bringing the energy under control and breaking the vicious circle The whole circumstances of his case were explained carefully both to the patient and to his wife, so that they were both completely aware of the situation With this understanding the patient's fear of himself diminished, while his wife realised how little was necessary on her part to put their whole married life on a right footing.

A second case will further illustrate this condition

The patient was a sister in charge of a ward in a large London hospital. Her history showed that she had been brought up very strictly She was engaged at 23 to marry a man considerably older than herself, but he died shortly afterwards, and her sex during this engagement had not been consciously aroused Her first knowledge of anything to do with sexual matters was from the lectures on venereal diseases, which was part of her nursing training The patient felt relieved that she had not married and she developed a horror of anything to do with sex

For two years previous to the onset of her illness the patient had been in a low state of health associated with a gradual impairment of her sight Her character about this time was said to have changed From being contented and good-tempered she became irritable, and in the last six months previous to her breakdown she became rapidly more restless The onset of the condition was sudden with restless wanderings and incoherence

The patient was put to bed in a nursing home, under the constant supervision of day and night nurses She was completely disoriented and dissociated, there were constant restless movements, a plaintive voice and a childish attitude.

Pauly reaction for histidine is strongly positive Tryptophane also appears to be present

Standardisation of the products described above was carried out upon young rats of uniform weight they were ovariectomised and swabs were taken daily for seven days, or until seven consecutive smears typical of di-œstrus were obtained The animals were then divided into batches of six and varying doses were given to each batch The unit was taken as the smallest dose producing cornification within 48 hours in a batch of six rats This work was carried out by Dr J Lee Warner, who also introduced an additional check by mating the injected females and noticing the presence of vaginal plugs He was successful in obtaining plugs with this new water-soluble material, but found that a greater dose was required to produce mating than to evoke œstrus This problem will be the subject of a separate communication

Summary

A method is described for obtaining the œstrus-producing hormone in a water-soluble form by extraction from placenta, the yield being over 1000 rat units per kg The activity of the preparation can be easily reduced to below 0 5 mg per rat unit Further work indicates that this degree of purity may be exceeded without much difficulty The properties of the new extract are discussed

THE PSYCHOLOGICAL TREATMENT OF MANIA AND DEPRESSION.

BY ERNEST SNOWDEN, M B , B S LOND ,

PSYCHOLOGIST TO THE HOSPITAL FOR EPILEPSY, MAIDA VALE, AND ASSISTANT IN THE DEPARTMENT OF PSYCHOLOGICAL MEDICINE, ST BARTHOLOMEW'S HOSPITAL

OF late years the treatment of certain cases of mental disorder without certification has become a practice amongst psychologists and the more advanced medical practitioners Cases of mental disturbance which would have been certified without hesitation only a few years ago are now recognised as being capable of treatment in their own homes or in an ordinary nursing home

The advantage of this to the patient is very great, so great that the physician is justified in taking a certain amount of risk in following this line of treatment so long as he is doing so with the cooperation of the patient's relatives It is important to realise that a patient need not of necessity be certified because he is certifiable

It is a fact that a great many cases of insanity can be prevented if they can be properly dealt with before the condition has completely developed Certification is a very serious matter for anyone The time will, no doubt, arrive when treatment in an asylum will lose the terror that is at present attached to it, but certification now means to the ordinary individual the giving up of the struggle, that from fighting his condition he is reduced to helplessness, that he has reached the lowest levels of mental capacity, and that his failure to overcome his illness is complete From this state the re-education process is slow and difficult, and the fact of certification leaves behind it a feeling of insecurity which must take many years for its removal, if indeed it ever disappears

To the ordinary individual the segregation of the insane patient is so absolute, he is cut off from his fellow men, and his life as a member of his community ceases It is for this reason that the lot of anyone recently discharged from an asylum is so hard He is returning to live in a tribe which has once turned him out Before he is readmitted to the life of the tribe everyone around him must be convinced that the condition which made his exclusion necessary will not return This state of affairs renders his return to ordinary circumstances more difficult, and produces in him a state of apprehension inimical to recovery It is the intention of this paper to consider two of the milder forms of psychosis and to show how these may be foreseen and prevented

The emotional states such as fear, sex, and anger are preparations for physical activity The natural result of the presence of something dangerous in our environment is that we should run away, and the condition that we recognise as fear is a preparation in the body to enable that escape to be effected Similarly, anything that threatens to injure some person or thing that we would naturally protect arouses us to a condition of body which we recognise in ourselves as anger These emotional states are, therefore, physical, and they are permitted a certain amount of expression in a civilised community, although they are not allowed to attain complete satisfaction Rage, for example, is discouraged and punished because of its danger to others, while anger, which is a controlled rage, is tolerated

Physical exercise assists in providing an outlet for the forbidden activity, while relief can sometimes be obtained by substituting one emotion for another For example, a soldier in the trenches who is afraid of the shells that threaten him and who cannot run away can attain some degree of relief by the physical activity of digging, or if this is denied him, by shouting or using bad language, or by some expression of anger In this last case an emotion (panic) which is not allowed by civilisation is expressed through the channel of an emotion (anger), of which civilisation is tolerant In this example it will be seen that there is something to express which needs an actual physical activity to express it

These activities are, for the most part, concerned with the motor functions of the body The digestive functions, and those functions which are associated with digestion, are left unstimulated and tend to stop, so that a stasis of the intestine occurs and a lowering of the activity of the liver These two changes have been mentioned as examples and to indicate the nature of the physical disturbance which is occurring If these changes happen frequently, the result will be an habitual stasis of the intestine, an increase of the dangerous intestinal flora, and an absorption of toxins which will increase the depression and so give rise to a vicious circle The commonest emotion and the one most likely, apart from the frequency of its occurrence, to bring about this state of affairs will be the emotion of fear It must be remembered that fear may be aroused by actual danger, by the recall of a terrifying memory, either consciously or in the form of a phobia, or by a purely imaginative process in which the patient pictures himself or someone belonging to him in a position of danger

It will presently be shown that the two conditions of depression and excitement are closely allied The chief difference between them seems to be that the depression state is the result of failure to secure any outlet for the physical activity which results from an emotional response, while the state of restlessness is an expression of that activity, not necessarily directed towards the object for which it was aroused, but possibly spread over all the events of the patient's life The cause of the condition is the same in both cases, being the control that is exercised by civilisation in preventing the expression of natural desires This control has also this effect, that it prevents the recognition by the patient in a great number of these cases of the actual desire which is being stimulated and so denies to him the opportunity of dealing with the difficulty for himself in a logical manner.

MANIA

Where the conditions of the patient's life are such as to produce a constant stimulus of one or other of these emotions there will result an activity in excess of the normal needs of the individual and the consequent development of restlessness excitability, and mania

Restlessness is an extremely common symptom in conditions of anxiety, and it is very frequently present in states of depression. Patients rarely complain of this symptom alone, but the fact that it exists is evidence of the presence of a stimulus of some kind strong enough to arouse activity in the motor mechanism A characteristic of it is that it leads the patient to expend more physical energy in the carrying out of any activity than the task demands or than would be needed by others for its performance Excitability is only a further degree of the same condition except that the energy is always present, ready to be fired off at the slightest stimulus and usually resulting in an expression of anger in circumstances where the ordinary healthy individual would exercise control. anger being as stated above, the emotional activity of which civilisation is most tolerant Mania is a condition in which control is largely in abeyance. In this condition the violence is expressed without any apparent outside stimulus whatever, and is often directed aimlessly upon animate or inanimate objects indiscriminately It will be of value to consider the bodily mechanism which underlies all this activity.

In considering the activity of the excitement state we must realise that apart from those functions which are directly or indirectly concerned with digestion or excretion, the whole body is involved, and it is obvious that there must be some mechanism at work more potent than that which is ordinarily employed in everyday life. The activity is so persistent so untiring. and in the acute condition of mania so violent, that it may go on to complete exhaustion and death This degree of activity could only be attained for a very short space of time if conscious effort were the only stimulus being employed It appears that the glands of internal secretion play a large part in this mechanism, and that the gland which is chiefly concerned is the parathyroid. This gland is said to be stimulated by the products of muscular activity circulating in the blood stream The parathyroid secretion produces an over-excitability in the brain-cells leading to a greater activity or preparedness for activity in the motor cortex This in turn produces a condition for which muscular activity is the only relief, and leads to the development of a vicious circle

Some such cycle as this would account for the restlessness in people who feel that they must constantly be doing something without pause, resting only when they are asleep, and achieving the state of sleep only with difficulty. This mechanism would account also for the phenomenon which has been observed by everybody—namely, the occurrence of sleeplessness at the end of a day when the muscles have been used more than usual and when the individual himself is actually very tired In the excitement state sleeplessness is a very common symptom, and the distress caused even in the milder forms of this condition by the experience of night after night of wakefulness is very great, and is one of the most important of the symptoms against which treatment must be directed In such cases rest in bed must be enforced until the vicious circle is broken, and the best sleeping draughts are those which act as depressants to the activity of the motor cortex

The following case illustrates the condition which has just been described

A man, aged 35, manager of a large factory, complained of restlessness with attacks of extreme excitability, amounting at times almost to maniacal outbursts. These were largely directed against his wife of whom he was very fond. He was restless at the office making work for himself when he might have remained unoccupied he was restless in his amusements only enjoying golf or bridge if there were high stakes to make the game exciting Between two rounds of golf he would hardly wait to finish his lunch before he was worrying his friends to start out again. He slept poorly The condition threatened his home life and made him acutely miserable. He realised that these outbursts of excitement were unreasonable and yet he was unable to prevent them, so that he was frequently morose and depressed. He believed that he would become insane and he feared that he might injure his wife in one of these excitement states

His family history was of importance His mother had deserted his father when the patient was only 5 years old, and the patient and his brother had been brought up by foster parents who were not particularly kind to them At the age of 14 the only kindness that the patient had received had been from his father's solicitor, who managed their affairs, and from this man's wife His father, who was an invalid, played a very small part in the patient's life and he saw him very little

The patient went to school in Ireland and was a keen Rugby football player At the age of 19 he believed himself to be in love with his guardian's sister who was 14 years his senior At that age he went to South America, where he was extraordinarily successful, and at the age of 23 he returned to England to join the army He had considerable experience as an infantry officer and then transferred to the R A.F where he took a pilot's certificate He then developed attacks of asthma and was eventually invalided out of the army When he was 26 he married his guardian's sister who was then 40 years old He realised that it was taking a definite risk for anyone of his age to marry someone so much his senior, but he felt compelled to take the step Soon after this he obtained his present employment as manager of some works abroad, where he was brilliantly successful.

He found that his wife, who had achieved considerable social popularity in the place where she lived, was one of those people whose chief object in life is to be a social success, and he conceived the idea that she was neglecting him in order to please other people. This habit of hers was a constant source of grievance to him and was the invariable cause of their quarrels She was quite unable to change her life-long habit, while he began to see neglect of himself in her most trivial actions He was obsessed with the idea that she must think of him first in everything; in fact, he behaved just as a spoilt child would do

The examination of his mind made it clear that he was looking upon his wife as if she were his mother and demanding of her a complete absorption in his affairs This attention she was either unable or unwilling to give, with the result that the patient developed the excitement symptom which was a manifestation of the energy which he might have used in primitive circumstances to insist upon her compliance with his wishes, but which his civilised mind endeavoured to keep under control This energy was expressed in the excitement condition in which he lived, his energy begetting more energy in the manner that has been described above

The *treatment* can be briefly described. He was put to bed in a nursing home and given sedative drugs, with the idea of bringing the energy under control and breaking the vicious circle. The whole circumstances of his case were explained carefully both to the patient and to his wife, so that they were both completely aware of the situation. With this understanding the patient's fear of himself diminished, while his wife realised how little was necessary on her part to put their whole married life on a right footing

A second case will further illustrate this condition

The patient was a sister in charge of a ward in a large London hospital. Her history showed that she had been brought up very strictly. She was engaged at 23 to marry a man considerably older than herself, but he died shortly afterwards, and her sex during this engagement had not been consciously aroused Her first knowledge of anything to do with sexual matters was from the lectures on venereal diseases, which was part of her nursing training The patient felt relieved that she had not married and she developed a horror of anything to do with sex.

For two years previous to the onset of her illness the patient had been in a low state of health associated with a gradual impairment of her sight. Her character about this time was said to have changed. From being contented and good-tempered she became irritable, and in the last six months previous to her breakdown she became rapidly more restless The onset of the condition was *sudden* with restless wanderings and incoherence.

The patient was put to bed in a nursing home, under the constant supervision of day and night nurses She was completely disoriented and dissociated, there were constant restless movements, a plaintive voice and a childish attitude.

If she was left unattended she would get out of bed and run from the room When spoken to firmly she would answer questions coherently for a moment or two, and then return to her dissociated state She was very exhausted by the persistence of the restless movements, which were only controlled by strong hypnotics, and she explained in a lucid moment that "it was more comfortable to keep moving than to lie still" (This statement by the patient is evidence that there is stimulation of the muscles through the motor cortex in such cases) She was obviously in a state of terror It was presently noticed that, although she occasionally spoke of suicide to the nurses, she always ran away from the open windows These were consequently closed and screwed down and very shortly afterwards the patient became more composed and made no more attempts to run from the room It was then possible to examine her mind more closely

The patient was able to explain that for six months she had had occasional attacks of dissociation, and that she had had *hallucinations of hearing* She heard sexual suggestions which were to her intolerable, and on several occasions she heard voices instructing her to take poisons from the poison cupboard which was in her charge She had found herself standing in front of the open poison cupboard without any idea as to how or why she had gone there She had been unwise enough not to consult anybody about it because she knew that she would have to give up her work if she did so The sexual hallucinations were in relation to a member of the staff of the hospital, whose attitude towards her had always been entirely professional, and to whom she had shown not the slightest sign of any such interest This is interesting as showing the development of the hallucinatory process Her repression of sex was so complete that she was apparently ignorant of sexual matters, and it was only in the form of an hallucination that her normal sexual wishes were able to gain expression, and this only by causing a complete breakdown of her ordinary conscious control and by producing a dissociation state It seems not improbable that the idea of suicide arose in consequence of the absence of response to her subconscious wishes from the man towards whom they were directed

Her recovery began with the dislike of surveillance, and this was gradually relaxed A slow change came over her personality during the first two days of the period during which she was returning to a normal condition, and she was weak and ill and depressed after this recovery The final recovery of her normal personality took ten days, and there was a complete amnesia for the whole period of her acute attack She did not then know the people who were surrounding her and expressed surprise at their friendliness and kindness

The period of her amnesia was then very cautiously recalled to consciousness, and she began to see without any outside suggestion that sexual wishes had been the cause of her dissociation, an idea which distressed her very much, and she recognised at the same time the true nature of the hallucinations

She was very restless and very conscious of her body This was controlled to some extent by means of luminal and medinal, while a mixture containing salix negra helped considerably to relieve the restlessness There was this change in her personality whereas she had been completely unselfconscious she was now shy and selfconscious She was persuaded to re-educate herself to these new circumstances, and she slowly succeeded in this endeavour, so that when seen three months later she was quiet and fairly well It was not until some eighteen months later that she was able to live anything like a normal energetic life again or to take up her life as a nurse once more

DEPRESSION

In some of these conditions the object for which the energy is aroused can be recognised and the energy liberated If a man is frightened he can run away By taking this natural course he uses up the energy that has been aroused, and his excited physical state is relieved If, however, there occurs a constant stimulus to one or other of the emotions and the complete expression of the emotion is denied, the excitement state gives rise to symptoms It is necessary now to consider those cases in which the energy can have no outlet, where there is no possibility of its being utilised, either because of the conditions in which the stimulus occurs, or because the stimulus is so opposed to the social ideal that it cannot be recognised This condition is probably the commonest cause of depression and melancholia and explains the reason why physical lethargy and helplessness, a form in fact of paralysis of the whole system, is so commonly associated with depression, and so often forms the most important symptom in melancholia

The circumstances leading up to this condition can best be illustrated by an example a wild bird if it is held in the hand will struggle to escape This struggle is the undirected activity of the instinct of self preservation, and if the bird is released at this moment it will fly away more rapidly and to a greater distance than it would do in any other circumstances If, however, the bird is held so securely that escape is impossible, after a few futile efforts to escape it will lie still in the hand A new phase in the struggle has now been reached Just as the effort to escape is the result of the stimulus to the instinct of self preservation and is automatic, the panic being stronger than the capacity for control, so, this stillness which succeeds it is an automatic process It occurs in all probability in order that the bird shall be prevented from destroying itself by its own attempts to escape, and is, therefore, not the result of reasoning The bird does not say to itself, "now I will lie still until a way of escape appears" It lies still because the "activity panic" has given place to a "stillness panic," which is equally an emotion, but which is associated with an inability to move If now the bird is freed, there is an appreciable interval between the time that it is free, and feels itself to be free, and the moment that it can summon sufficient energy to fly away. This shows that the inertness which developed to prevent useless activity lasts beyond the need for it, and has a tendency to prevent the reappearance of the normal activity when the way for escape lies open Instances such as this in the animal kingdom can be multiplied to almost any extent

If the same circumstances affecting the human animal are observed a similar condition of affairs will be noticed Fear, in man, the result of the stimulus to the self-preservation instinct, is normally followed by running and a search for somewhere that is safe If, however, the stimulus persists over a longer period and the conditions are such that there is no escape and no possibility of escape, then the physical state becomes one of stillness and inertness similar to that shown by the bird when it is closely held in the hand

It may be that in primitive circumstances this stillness would be imposed upon us in order to assist us to escape observation We observe it in ourselves when we are awakened from a deep sleep, at night, by something unusual that has occurred We lie rigid, with the heart beating rapidly and the breathing diminished and shallow This rigidity is automatic The soldier in the trenches, who is terrified by shell fire and cannot escape, will collapse into a semi conscious state in which he cannot walk unaided He will not speak nor be persuaded to eat or drink, and he may remain in this condition for hours or days

The foregoing is a description of an acute condition of helplessness, a condition aroused by something actually alarming which occurs in our environment, but we are more concerned here with the chronic form of this acute condition If a means of escape is provided for panic, the violent activity of running is observed, whilst anxiety can be looked upon as chronic fear, and is associated with over-activity of the muscles and restlessness In a like manner the chronic state of the "stillness" reaction is associated with an inertness and incapacity for exertion of any kind It must be looked upon as a reversal of the ordinary activity which follows the stimulus of an instinct, and the same rules will apply when the emotion that is aroused is sex or anger Examples of this reaction occurring in every-day life are not difficult to find

The patient is afraid of an illness, say, for example, of cancer, or what is perhaps still more terrifying, of insanity, due to an inability to understand his physical or mental symptoms There is no escape, he cannot run away from himself, and because there is no escape, inertness, helplessness, and grief replace muscular activity, restlessness, and excitement In the case of the young girl jilted by her lover, her sex is prevented from achieving the end for which it was aroused, and there is no escape from the situation The excitement and happiness of courtship is replaced by the inertness and helplessness of grief

With these examples before us it is easy to understand the symptoms of depression and of melancholia The muscle weakness is accompanied first by a disinclination to activity and finally by an inability to move, and when the patient has reached this stage no stimuli are of any avail because it is not a question of "will not" move but of "cannot" move The last state of the illness is shown by the melancholic who sits "in a heap" all day long resenting the approach of any one for fear he should be called upon to make some effort of which he is physically incapable

A disturbance of the digestion follows The appetite goes and food is refused. and finally all attempts at persuasion are resisted and forcible feeding has to be resorted to in order that the patient may be kept alive Although it must be recognised that this feeding is necessary in some cases it should be remembered that the condition is first of all developed at a time when the patient is unable to utilise the food that he forces himself to take.

Every function of the body becomes lowered in the same way as those which have been used as examples so that depression and to a greater degree melancholia are found to be associated with a lowered activity of endocrine glands and. in consequence with a lowered bodily temperature and a feeling of misery. Finally, because the general condition is working at such a low level there results a greater liability to certain diseases and a lessened capacity to resist them

These considerations of the causes that lead to depression and melancholia give us the clue to their treatment In examining such a patient we will find that there has occurred in his life some circumstance which has prevented the normal expression of one or other of his emotions and it is necessary. if he is to be saved from the development of the depression state. that this circumstance should be recognised The cause of the condition should be explained to the patient who is probably unaware of it and if possible his circumstance should be changed in order that the emotional stimuli shall be prevented or that the emotional responses may be given some outlet This will help to check the onset of the helplessness and will enable the rehabilitating natural activity to reassert itself

It is obvious that this work must be done in an earlier stage than the stage of melancholia. The melancholic can give us no information he resents our presence and our interference, because it is usually the precursor to some demand that he shall make some effort, and he feels incapable of making any effort.

The above description of depression and melancholia rather emphasises the physical elements in the condition and it is important to bear in mind that these states are physical that the depression state that appears in the syndrome as a mental symptom arises from the physical condition of helplessness which is a direct and automatic result of the inability of some conscious or subconscious wish to gain expression

PHYSICAL AND PSYCHOLOGICAL TREATMENT.

The correct treatment of the patient from the physical point of view is of very great importance The conditions here described and particularly the state of depression. have the effect of interfering with the general metabolism of the body. The digestion is slow and incomplete and there is in consequence increased infection in the intestine. largely the result of an increase of the *Streptococcus salivarius* Substances of a toxic nature the elimination of which is difficult circulate in the blood stream and there is sometimes a peculiar odour about these patients which probably emanates from this source

Apart therefore from the treatment of the patient in bed and in one room, attention must be given to diet and elimination High colon wash-outs should be practised every day and large amounts of bland fluids should be taken in order to assist in the elimination of toxins Lemon water. barley water and magnesia drinks should be given as much as the patient can stand Baths are of value particularly in the states of restlessness and mania Where the restlessness is extreme a prolonged tepid bath each day will often have more effect in soothing the patient than the exhibition of any drug

The essential factor in the psychological treatment of these cases is that they shall be under close observation. and that circumstances shall allow of a prolonged visit from the psychologist every day. It is only by sitting down with the patient and watching him very carefully that any control can be brought to bear upon him No matter how dissociated the patient appears to be it is usually possible for the influence of the presence of the physician to arouse whatever is left of the patient's reasoning capacity. It gives the patient something to hold on by. Every effort should be made to produce in the patient a feeling of security He must be made to feel that those around him are endeavouring to help him and that they have a belief in his recovery. If the patient is able to attain this feeling of comfort and support he is more likely to be communicative and as his recovery proceeds he is better able to accept the assurance of the physician as to his condition

The psychological examination of the patient should not be attempted until his confidence has been won and until this feeling of security has been attained. Apart from this he must have reached a state of physical health approximating to normal Attempts to press this examination forward too rapidly are likely to end in increasing the strain from which the patient already suffers. The point at which the patient reaches this stage in his recovery is a matter for experience and gentle trial to decide Sometimes it will be found that the first recall of the patient's circumstances after he has been separated from them for some time will result in a recurrence of his symptoms and if this should happen the mental examination must be postponed and a further trial attempted when the patient is stronger. Treatment away from the surroundings that have given rise to the condition may prove to be all that is necessary to restore the patient to health. but unless some adjustment has occurred during the patient's absence from these surroundings. which relieves him from the strain that has caused the condition the cure is never permanent It is for this reason that the psychological examination must be carried out. the cause of the illness explained to the patient. and the circumstances altered if possible

A case will illustrate this.

A married woman aged 47, complained of inability to concentrate. forgetfulness depression and irritability with restlessness. She was intensely self-depreciative and felt that she was a burden to her husband and children, and on several occasions she had wandered away from home in a vague manner, while she constantly dwelt upon the idea of suicide. She avoided meeting people, became unable to manage her home and was inclined to avoid her husband and children of whom she was very fond.

Her history showed that she had been a nervous girl and that before her marriage she had been daily to business in London. She married a man who had been educated at Oxford and whose people were of importance in the locality where they lived She got on badly with her husband's mother who no doubt was at no pains to hide her feeling that her son had married beneath him. Her children were growing up the daughter was going to a finishing school abroad and the son to a public school so that during the period immediately preceding her illness she had been left with very much time on her hands Her husband had for a great many years taken a very keen interest in amateur theatricals and was away from home at night This had all tended to throw the patient upon her own resources and she had not been sufficiently well educated to know how to make use of her leisure

Careful examination revealed that she had through the whole of her married life felt herself to be inferior to her husband and lately to her children as well. It appeared that several factors went to the production of this state of depression Her husband's social activities had grown while she was bringing up the children, and now, although she had them no longer to occupy her time, she could not take an interest in his amusements It was as if someone belonging to her had been taken away from her, and her instinct would, consequently, be to keep him at home Her conscious reasoning saw that these relaxations of his were innocent and good for him, so that conflict occurred between these two ideas She may have been prevented from interfering with these pursuits of his by the fear that her presence might not be welcomed by her husband's friends In any case, the fact remained that she was unable to keep him at home and consequently her instinct to do so was denied its outlet It is probable that this conflict had been going on for the greater part of her married life, and only presented difficulties when the companionship of her daughter was lost

How far her age was of importance in the production of this condition it is very difficult to say It has been the practice to describe these cases as menopausal The patient was still menstruating, but at irregular intervals, and it should be kept in mind that in such cases the mental disturbance has been existing for many years previous to the onset of the menopause, and that a debilitating illness is quite as likely to produce the same effect It is common for cases of this type to date from an attack of influenza, which is looked upon by the patient as the cause of the illness, although the real reason for the appearance of the symptoms at this point is that the lowered condition of the body, caused by such an illness as influenza, lowers the resistance of the patient to the mental disturbance and enables the symptoms to appear The menopausal factor must, however, be considered in treatment, and the administration of gland substances to support the whole gland system must be added to the general treatment of such cases

Apart from the nursing home and general treatment usual in these cases, the whole situation was explained to both the patient and her husband After she had been in the nursing home for some weeks and was beginning to recover her strength, to take an interest in books, and to begin to make plans for the future, her husband was advised to come up to town and to take her out to dine and to the theatre, and she was allowed to spend Christmas with him in an hotel in London The physical fatigue caused by these expeditions was more than counterbalanced by the degree of mental comfort that she obtained by having her husband to herself Eventually she was able to return home and take up her life again Relief to her mind enabled her to overcome the physical state occasioned by grief, and she made a complete recovery. despite the fact that the menopausal symptoms still persisted

This type of patient is usually classed among the psychoses, because the behaviour in the acute stages requires so much supervision and control, but with proper treatment it is possible to recover No obvious changes are shown in the nervous system, except where these occur as a result of the toxins circulating in the blood stream These changes are not, as a rule, of a permanent nature unless the condition is permitted to persist for a very long time Properly treated in the earliest stage of the illness, these changes in the tissues are mild in character and only temporary in their effect

THE EFFECT OF THE ADMINISTRATION OF SODIUM BETA-HYDROXY-BUTYRATE ON THE GLYCOSURIA OF PHLORIDZIN DIABETES

BY NOAH MORRIS, M D GLASG,
AND
STANLEY GRAHAM, M B TOR

(From the Medical Department, Royal Hospital for Sick Children, and the Institute of Physiology, Glasgow)

THE question of the conversion of fat into carbohydrate by the animal organism has been one of great controversy for many years Most authorities agree that so far as the vegetable kingdom is concerned this change can occur, but in animals experimental proof is still lacking and opinion is divided Lusk,[1] for instance stoutly denies that such a transformation takes place, and certainly many of the experimental results justify such a conclusion Geelmuyden,[2] on the other hand, believes that sugar can be formed from fat by the animal organism and he quotes experiments in which he has found a distinct rise in the sugar output as a result of feeding acetone bodies to rabbits In a series of injections of sodium acetoacetate and oxybutyrate to phloridzinised dogs, Marriott,[3] however, failed to find any increase in the output of glucose

In the resting state it has been shown that, on the basis of oxidation of fats to CO_2 and water, it is possible for the tissues to make use of the energy liberated in this way Murlin and Riche[4] showed that the intravenous injection of an emulsion of fat led to an increased heat production together with a fall in the respiratory quotient In the case of external work however, there is no evidence that muscles can use fat directly, although it has been clearly shown that they utilise glycogen Benedict and Cathcart[5] have demonstrated that during muscular exercise fat and carbohydrate are apparently equally well utilised, and the work of Krogh and Lindhard[6] indicates that muscular work can be performed at the expense of fat in the diet

Recently Hill, Long and Lupton [7] have shown that the respiratory quotient of excess metabolism during short periods of exercise is unity, irrespective of diet This indicates that, although fat in the diet may be used up during muscular exercise, the muscles themselves can only utilise carbohydrate

If carbohydrate is the sole source of energy for contracting muscle, and if fat is utilised in the performance of muscular work, the conclusion appears inevitable that fat must undergo a preliminary conversion into carbohydrate previous to its use by the muscles. Geelmuyden [2] also suggests that fats are transformed into carbohydrate via a ketone body stage, the transformation taking place in the liver This hypothesis seems reasonable when one considers that in all conditions where energy is obtained mainly from fat, as in starvation and during the administration of ketogenic diets, acetone bodies appear in excess in the blood and urine

If this be true the administration of acetone bodies to a dog rendered diabetic by means of phloridzin might be expected to cause an increase in the output of sugar This could be readily detected by a rise of the dextrose-nitrogen ratio in the urine, since in a completely phloridzinised animal all the glucose is presumably derived from the protein

Two Experiments

The following experiments were performed in order to find out whether any support could be adduced for this hypothesis Sodium beta-hydroxy-butyrate, prepared by neutralising the racemic beta-hydroxy-butyric acid with sodium hydroxide was used It was unfortunately impossible to obtain the lævo-rotatory acid The same dog was used for both experiments, and on each occasion received a constant diet of 500 g of minced meat twice daily Phloridzin in olive oil was given subcutaneously in one gramme doses twice daily on each day of the experiment The butyrate was given by stomach-tube at the end of the third day In the second experiment a small amount was vomited shortly after administration so that probably not more than 15 g was retained The animal was catheterised at the end of each 24-hour period to ensure accuracy of the 24-hour sample of urine

EXPERIMENT 1 —*Female Dog; weight 8 8 kilos*

EXPERIMENT 2 —*Female Dog; weight 9 3 kilos*

Day	Total nitrogen	Sugar output	D N ratio	Day	Total nitrogen	Sugar output	D N ratio
1st	14 3	43 1	3 01	1st	29 2 *	82 0	2 80
2nd	15 0	47 1	3 14	2nd	17 1	87 7	5 12
3rd	16 1	52 6	3 26	3rd	18 5	93 4	5 05
25 g sod beta hydroxy-butyrate given				20 g sod beta-hydroxy-butyrate given Slight amount vomited			
4th	17 9	51 0	2 84	4th	17 4	95 2	5 47
5th	17 5	55 5	3 17	5th	16 5	96 1	5 82
6th	16 8	53 7	3 20	6th	19 7	109 8	5 57
7th	14 7	45 4	3 08				

* Done in triplicate

In neither of the above experiments did the butyrate cause an appreciable rise in the D·N ratio, thus agreeing with the results of Marriott[3] Unfortunately we used only the racemic acid, and we feel that the results might have been more conclusive if we had also given the lævo-rotatory variety. Marriott suggests that, because the acid present in the urine is the lævo-rotatory form the body can only use the dextro-rotatory type, a conclusion which is scarcely warranted

Whether the butyrate can be changed into sugar or not still remains an open question Certainly no evidence of its conversion into sugar is afforded by the two experiments above The experiments of Magnus-Levy[8] suggest that because of the phloridzinisation the animal might be incapable of burning the ingested beta-hydroxy-butyrate.

Also, it is quite possible that the extra sugar might have been stored in the muscles as glycogen, to be used during muscular exercise later on As blood-sugar and presumably urinary sugar cannot be derived from the muscle glycogen there would be no change in the D N ratio

A further point of interest is that in the two experiments in the same animal under identical conditions, the D N ratio should show such a marked difference

We wish to acknowledge our thanks to Prof D. Noël Paton for performing the operation of perineotomy and for his helpful advice, and to Prof Leonard Findlay for his kindly criticism

The expenses of this work were defrayed by the Medical Research Council, which we wish to express our gratitude

B FALLAX IN CHRONIC ARTHRITIS.

BY J MUTCH, B A,

AND

N MUTCH, M D CAMB , F R C P LOND ,
ASSISTANT PHYSICIAN, GUY'S HOSPITAL

IN the course of an investigation of the bacteriology of chronic arthritis, cultures were made from joints excised by Mr W H Trethowan for orthopædic purposes Very great care was taken during the operations to prevent contamination of the instruments and tissues by air-borne organisms The material, which consisted of cartilage in various stages of erosion, ligament, and synovial membrane, was cut into small pieces These were incubated aerobically at 37° in simple and in glucose broth Frequently every tube remained sterile, in certain instances pyogenic cocci grew, and in one case a pure culture was obtained of *B fallax*, an organism which has been isolated occasionally in the past from gangrenous wounds and cases of puerperal septicæmia There is no record in the literature of chronic joint infection by this bacillus, so that the following details are of interest

The material was obtained from a woman of 53 with chronic arthritis of several years' duration affecting both knees The synovial membrane was much thickened, but there were no definite osteophytes, and limitation of movement was due chiefly to pain

Isolation and Identification of the Organism.

The original cultures, made in broth, glucose broth, and on blood-agar, were incubated aerobically at 37° C In two tubes of glucose broth a pure culture of a Gram-positive bacillus grew The other tubes remained sterile Subcultures in the absence of the pieces of actual tissue present in the original tubes yielded growths only under strictly anaerobic conditions

The organism, a short Gram-positive, very slightly motile bacillus, was a strict anaerobe Spores were never seen in young or in old cultures, but growth could be obtained from week-old blood-agar cultures which had been heated to 80° C for ten minutes

Blood-agar —Growth slow and after 48 hours formed a fine grey film

Glucose broth —A fine opalescence after 48 hours

Broth and agar —Very little growth

Litmus milk —Slow acid formation Seven to ten days required for clotting

Sugar reactions (1 per cent sugar in litmus broth) —Gas production inconspicuous (Table I)

TABLE I

—	24 hours	12 days		Evidence of growth

Starch	„	„	—	„
Dulcite	„	„	—	Subculture
Glycerine	„	„	?	No growth visible or in subculture

Agglutination Reactions

By the courtesy of Dr M Robertson, of the Lister Institute, standard cultures were obtained of several anaerobic organisms resembling the bacillus under investigation and were grown for three days in glucose broth After centrifuging, the deposit was diluted with saline until each cubic centimetre contained 500 million bacilli, and was injected into rabbits at intervals of seven days: first dose 1 c cm , second dose 2 c cm , third dose 3 c cm. The animals were bled ten days after the last inoculation and the agglutination reaction tested as in Table II , where it is shown that *B fallax* (Morcom) serum agglutinated *B fallax* (Morcom) itself and the bacillus Z under investigation in very high titre. Investigated organism Z serum agglutinated organism Z itself and *B fallax* (Morcom) in very high titre. No other agglutinations of any note were observed.

TABLE II

Organism	Serum				
	Normal (1)	Normal (2)	*Z*	*B fallax*	*B fallax* (Morcom)
Bacillus Z*	0	0	1/2000 in ¾ hr	0	1/625 in 2 hrs
*B fallax**†	0	0	0	1/125	0
B fallax (Morcom)*†	0	1/5	1/2000 in 55 mins	0	1/625 in 20 mins
B tertius†	1/5		1/25		
B cochlearis†			0		
B welchii†			0		

* Under investigation † Lister Institute

It is evident that the organism forms agglutinins readily and closely resembles the strain *B fallax* (Morcom) kept as a type culture at the Lister Institute. It seems justifiable, therefore, to classify it as *B fallax*.

Infectivity

Thick saline emulsions made from 24-hour cultures on blood-agar were injected intraperitoneally into mice without causing death or any appearance of illness. Several mice were killed at the end of 24 hours and cultures made from the blood, spleen, and peritoneal cavity. These remained sterile, except in the case of one mouse which showed a little fibrinous exudate on the liver. Cultures from this exudate gave a pure growth of an anaerobic Gram-positive bacillus resembling the original organism and agglutinated in high titre by *B fallax* (Morcom) serum and investigated organism Z serum.

Intramuscular injections in guinea-pigs did not yield any living organisms in cultures made later from the tissues at the site of injection.

The organism clearly possesses infective powers, but under experimental conditions these are not of a high order. This agrees with the findings of other observers working with strains of *B. fallax* isolated from wounds.

Clinical Consideration

Agglutinins are formed readily in human subjects. Dead organisms were employed in the form of a simple Wright's vaccine. Doses ranging from one million to 500 million were given in series and agglutination reactions tried five days after the inoculation (Table III).

TABLE III

—	Normal serum	Serum after course of vaccine
Original organism	No agglutination	1/200
Organism after passage through mouse	Ditto	1/600

A similar vaccine was used subcutaneously in the treatment of 47 patients with chronic arthritis (venereal disease, gout, and tuberculous infections were excluded). The series must not be regarded as representative of the general community. Most of the patients had already been treated by autogenous vaccines and elimination of septic foci and belonged to the residuum which fails to reap substantial benefit from this type of treatment.

The results were of three kinds:—

1. In a number of cases small subcutaneous doses—e g, one million bacilli—provoked intense reactions in the joints, and precipitated a transient attack closely resembling acute rheumatic fever of children. The severe reactions were not repeated with subsequent inoculation in the same patients, and were invariably followed by rapid improvement in the condition of the joints. All of these patients had previously had autogenous coccal vaccines without experiencing reactions of like nature.

2. The majority of patients improved steadily, and the pain reaction which commonly follows injections of autogenous vaccine made from pyogenic organisms was frequently replaced by its converse, a phase of gratifying freedom from pain lasting for several days.

3. A small but definite group of patients did not improve, and did not experience abrupt reactions, the transient phase of ease from pain or even (except in one instance) pain reactions in the joints.

The results can be tabulated as follows:—

	Per cent
Abrupt febrile reactions after small subcutaneous doses	8
Simple pain reactions	35
Period of ease after each inoculation	39
No immediate change	18
OR	
Complete arrest	12
Decided benefit	70
No relief	18

Conclusions

It has been impossible to determine by direct bacteriological methods whether *B fallax* is a common cause of arthritis or only an occasional inhabitant of diseased joints, but the clinical manifestations following the use of the corresponding vaccine suggest strongly that this infection is much more prevalent than might have been imagined. There is no evidence that it is the universal infective agent, and in the series under review exceptional cases occurred in which improvement was steady under autogenous coccal vaccines, came to a standstill when *B fallax* was substituted, and yet recommenced when *B fallax* was discarded and the autogenous vaccine employed once more. The best results were obtained in the more chronic varieties of arthritis and in the treatment of residual pain and swelling in joints which had been more acutely inflamed but had passed into a sluggish phase after improving up to a point.

One such case is of particular interest. At the onset of illness there was much pyrexia with staphylococcal septicæmia, a large turbid exudate in the pleural cavity, and severe multiple arthritis. *Staphylococcus aureus* was obtained from the blood and from the chest. The corresponding vaccine provoked such intense reactions that its use was discarded for a time in favour of a polyvalent anti-staphylococcal serum. As the pyrexia subsided, the man was left with chronic multiple arthritis indistinguishable clinically from that often classified as rheumatoid arthritis. In this phase his autogenous vaccine helped materially for a number of weeks but finally failed to be of any assistance. *B fallax* vaccine was given and produced pain reactions in the joints. The man improved rapidly and in a few months' time was ready to return to work. In this patient it appears to be quite certain that the original invader of the joints was a pyogenic coccus. The benefit obtained from *B fallax* in the later stages suggests that this organism was a secondary invader.

The effects following the use of *B fallax* have been so impressive that it would seem advisable to add this organism to the autogenous vaccine in the treatment of chronic arthritis, especially when the joints have been damaged previously by injury or coccal infection or are the seat of disease which has been non-pyrexial and insidious from the onset.

Some time ago a series of 200 cases was analysed in which the importance of streptococcal infection of the digestive tract was discussed. Recently a further series of 103 cases has been treated on similar principles, but with the addition of *B fallax* to the autogenous vaccine. The results have been distinctly better, and the method represents a definite advance in the therapeutics of the condition.

Clinical and Laboratory Notes.

ULTRA-VIOLET IRRADIATION IN GANGRENE

BY PAUL BOUSFIELD, M R C S ENG,
LATE PHYSICIAN TO THE LONDON NEUROLOGICAL CLINIC, MINISTRY OF PENSIONS

THE following case has interesting features —

The patient was a woman aged 92 Her regular physician had been called in on account of a subacute attack of bronchitis, but on examining her back he found two large patches of dry brown gangrene which involved the skin and superficial fascia Round the edges of the gangrenous patches, which had retracted, there was about a quarter of an inch of raw flesh from which was oozing blood and a small amount of pus One of the patches of gangrene was over the right scapula; it was oval in shape and had an area of about 15 sq in After the slough was removed the depth of this lesion was about an eighth of an inch The other patch was over the posterior aspect of the head of the right humerus, and was about 4 sq in in area, after the slough had been removed the wound was a quarter of an inch in depth. There was also an oozing bedsore with an area of 2 sq in. over the upper part of the sacrum

The history of the gangrenous patches was interesting The old lady had been in the habit of sitting upright in a chair with a stiff, high, wooden back, against which she leaned on her right side for hours at a time in order to look out of the window The pressure had evidently occluded the blood-vessels in the gangrenous areas

Her condition was aggravated by renal insufficiency and cystitis of some years' standing, and her physician naturally took a very grave view of the case Knowing the effect of ultra-violet irradiation on small ulcers he asked me if it was likely to be of any use in this case I consented to test its effect, though I hardly considered in such a patient that it was likely to be completely successful. The gangrenous sloughs were first removed by repeated fomentation and with the help of scissors and forceps, with the result that the two raw excavated surfaces, described above, were left bare I then proceeded with the irradiation, using a portable arc which required 5 amperes at 240 volts to work it The current at the patient's house was unfortunately an alternating one, and I was therefore only able to use iron-cored carbon electrodes instead of tungsten which I should have preferred I mention this because the electrodes I used only develop an ultra-violet spectrum down to about 3000 A.U. wave-length, whereas tungsten electrodes reach as far as 1800 A U wave-length, and it is in this latter portion of the spectrum that the bactericidal rays are developed This is noteworthy because after two treatments the pus had completely disappeared and did not again return, in spite of the fact that the patient repeatedly pulled off her bandages

I began with a dose from the open arc at a distance of 3 ft for a quarter of an hour, irradiating the whole back, but using a concave mirror so as to focus radiant heat directly upon the open wounds The same dose was repeated in 48 hours, and thereafter was gradually increased up to 20 minutes, and the arc brought to within 18 in of the wound After the first two treatments the pus had disappeared After four—i e, at the end of ten days—new skin had formed half an inch all round the larger wound, and both wounds were covered with healthy granulations The oozing of blood, which had been continuous at first, had also completely ceased After eight treatments—i e, three weeks—the large wound was entirely covered with skin except for a small patch about the size of a sixpence in the centre, and the small wound had developed about half an inch of skin round the margin Granulations in the centre of this wound were proliferating too fast and had to be touched with copper sulphate At the end of about six weeks both wounds were completely covered with healthy skin, and the bedsore over the sacrum, which had also been treated, was completely healed

A noteworthy side-issue was the great improvement in the general condition of the patient When first seen, and for a month or so previously, she had been in a dazed and sometimes rather comatose condition, at the end of the treatment she was bright, cheerful, and intelligent.

The case is particularly interesting in that it suggests that bedsores in old people, which so frequently usher in the terminal event where bad nursing has preceded the physician's arrival, may now be more amenable to treatment

DIASTATIC REACTION IN OBSTRUCTIVE JAUNDICE.

BY JOHN D. THOMSON, M.B, C.M.

IN May, 1922, when engaged in investigating the efficiency of the pancreas and liver in cases of sprue at the Seamen's Hospital for Tropical Diseases, London, I was asked by the resident surgeon if any of the biochemical methods I was employing would be likely to throw light on an obscure case of obstructive jaundice that was then causing anxiety Although several years have since elapsed I am led to believe that a few details of this case, suggesting the more general use of a very simple test, may be of interest

Recent History—The patient, an adult male well over middle age, had been operated on for gall-stones some weeks before his case was brought to my notice The gall-bladder had been emptied of calculi and drained In the ordinary course of events bile should now have been present in the stools and the drainage-tube dispensed with. As it was, there was still no trace of bile in the stools, and the tube draining the gall-bladder had to be retained The patient was losing ground and his general condition now suggested malignant disease (? cancer of the head of the pancreas) to the surgeon who had operated I understand that the surgeon had satisfied himself, by passing a probe at the time of operation, that the common duct was free and that all calculi had been removed

Diastatic Reactions—The diastatic reaction of the patient's urine would, I thought, throw some light on the case, and I offered to do a series of such reactions if necessary. The results were as follows:—

Date of examination	Result.	Date of examination	Result
May 19th	D =10–20	June 7th	D.=25
May 30th	D =66	June 8th	D =66.
May 31st	D =300	June 12th	D =100
June 6th.	. D =100	June 14th .	D =100

On May 19th the diastatic reaction (D=10–20) was normal, which showed that there was no obstruction to the flow of pancreatic juice into the bowel As bile was draining freely from the drainage-tube in the gall-bladder while there was no trace of it in the stools, the site of the biliary obstruction could be located with certainty as being then in the common duct somewhere below the entrance of the duct from the gall-bladder and above the entrance of the pancreatic duct

Some days later, as the patient's condition did not improve but rather grew worse, the examinations were resumed On May 30th the reaction (D = 66) showed that the obstruction now partially involved the pancreatic duct On May 31st pancreatic obstruction was complete At this stage I asked the house surgeon to keep a sharp look-out during the next few days for the appearance of bile and for the presence of a gall-stone in the stools But biliary obstruction remaining complete as before, the examinations were again resumed, and the results from June 6th to 14th clearly show that pancreatic obstruction, from being complete on May 31st, eased off until it reached a minimum on June 7th It again increased until, on the 12th and 14th, it was of the same degree as it had been on June 6th

This indicated a ball-valve action so far as the pancreatic obstruction was concerned, and made it reasonably certain that the biliary obstruction was due to a gall-stone that had passed along the common duct, and was now caught in Vater's papilla This diagnosis was confirmed by the surgeon, who now operated a second time and removed a gall-stone from the site indicated The patient made a good recovery, and there was no further sign of biliary obstruction Incidentally it may be remarked that these diastatic reactions showed that the kidneys were normally efficient

A CASE OF
FACIAL PARALYSIS OF AURAL ORIGIN
IN AN INFANT SEVEN WEEKS OLD

BY NEILL HOBHOUSE, M B OXF, M R C P LOND,
PHYSICIAN TO OUT PATIENTS TO THE VICTORIA HOSPITAL FOR CHILDREN,
AND
C JENNINGS MARSHALL, M S LOND, F R C S ENG,
ASSISTANT SURGEON TO THE HOSPITAL

THIS case seemed to us to be worth recording, as we have not known of a similar one occurring in infancy.

The child was born after a normal confinement, without instruments, and seems to have been normal in every way until, at seven weeks old, it was noticed that the left side of the face did not move when she cried She was seen by one of us (N H) at the Victoria Hospital for Children on Jan 21st, 1927 There was marked diminution of movement on the left side of the face, but paralysis was not complete The eyelid remained almost immobile in a half-closed position, otherwise the cranial nerves were normal. There was no discharge from the ear, and no indication of pain in any situation, and the child did not appear fretful The only abnormality detected was a slightly enlarged pre-auricular gland on the left side The mother stated that the child was still able to suck, though rather more slowly than before

Aural examination (C J M) showed that the drum was opaque and hyperæmic, with pronounced bulging No mastoid tenderness or œdema was present The right drum was normal There was nasopharyngeal muco-pus, but no gross adenoid vegetations On paracentesis of the left drum pus welled up in sufficient quantity to fill the external meatus Rapid healing of the drum, with complete recovery of the otitis, ensued The infant, seen just over two months later, showed no trace of facial paralysis, the drum was slightly more opaque, and the scar of the incision was just visible

The inflammation of the nerve must have occurred in the middle ear, in the aqueduct Considering the negligible size of the mastoid antrum at this age, the locality in which so large a quantity of pus was contained is rather difficult to determine A remarkable feature of the case was the very slight interference with the function of sucking which the facial paralysis produced This suggests that the part played by the facial muscles in the mechanism of sucking is less important than has been supposed, and that this function is almost entirely carried out by the muscles attached to the mandible and innervated by the fifth nerve

Medical Societies.

ROYAL SOCIETY OF MEDICINE

SECTION OF ORTHOPÆDICS

A MEETING of this Section was held on May 3rd, Dr W T GORDON PUGH, the President, in the chair

MR NORMAN D ROYLE (Sydney) read a paper, illustrated by epidiascope and cinematograph on the TREATMENT OF SPASTIC PARALYSIS BY SYMPATHETIC RAMISECTION

His purpose, he said, was to give some ocular proof of the results of this operation He had read the criticisms of the method which had emanated from Britain and America, and he found that in the United States, which he had just visited, the operation was almost universally accepted Harvey Cushing certainly favoured the idea

Dealing first with the results he had obtained in animals, Mr Royle said that the immediate effect of cutting the sympathetic nerve was to cause vaso dilatation, in a thin subject this was evident as soon as the nerves were cut, whereas in a fat subject it might not become established for an hour or two Also there was a definite change in temperature after the section—in one case as much as 7° F The next observed result was a change in muscle tone, which was brought out in the cinematograph film Before operation the patient's reflexes were rapid and jerky, but the muscle tone, as described by Holmes and Walsh, disappeared after sympathetic ramisection The goat was a good animal on which to show these changes In a general way, too, the limbs from which the sympathetic nerves had been removed behaved differently from the limbs in which they were intact

A patient, whose leg after operation comported itself as if it had no tone at all, said that before the operation he was unable to relax, whereas now he could do so This meant that before being operated upon, if his leg went out into a position of extension the only movement was a reflex one, and when the reflex movement was elicited he was unable to let go It was useful to consider how muscle tone was controlled normally Under ordinary circumstances a person had no control of muscle tone, excepting as a concomitant of active movement, the eye could be opened or closed, but when open it remained more or less in the same position without intervention, it could not be made more fixed nor less fixed In lesions of the nervous system the patient might lose control over his phasic movement, secondly, he lost the power of letting go of his muscles In addition there was a release of function in the centres controlling movement and in those controlling tone If under ordinary circumstances we had no control over tone, then under these abnormal circumstances tone became an obstacle to movement And this affected all groups of muscles, not only the extensors, but, in spastic paralysis, the flexors also Mr Royle showed on the film one patient who before operation had no control over movement, but in 20 days thereafter showed considerable control In examining these patients he said it was important to distinguish between clonus and lengthening and shortening reactions

One patient whom he had had under control many years had previously had Stoffel s operation performed for the adductors and flexors of the knee, and for the peroneal group of muscles, but it had not given her balance The result given by ramisection within a month was much more satisfactory than the other procedures had given in the course of years, even though attempts at educating the muscles had been patiently carried out The defect was a congenital one

The next patient shown had such a useless right upper limb that he was unable to distinguish one sensation from another, and could not open and close the hand On the day following the operation, however, he was able to close his hand on the bandage

A further patient had considerable abductor spasm, and in addition to ramisection Mr Royle had lengthened the hamstring muscles Nothing had been done to the adductors, 12 months after operation the patient was able to walk without aid other than that of a stick.

A woman, aged 23, with congenital spastic paraplegia, showed extension of the foot and dorsiflexion in coördination with the knee The knee-jerk was brisk. Six weeks after bilateral sympathetic ramisectomy she was able to walk supported by two sticks; she had never walked before She could also balance

The subsequent history of this patient was interesting, said Mr Royle, in view of the work of the Russian *school. which had shown that removal of the* sympathetic made patients more able to resist fatigue This young woman had at first been able to walk only a few yards, subsequently she improved so that she could now walk for miles These patients were able to walk because something had been taken away which prevented inhibition Where contractures existed, his *plan* was *to* perform sympathetic ramisectomy on one side, dividing the hamstring muscles, lengthening the tendo Achillis and indeed doing whatever was necessary, at one sitting on one side. A boy on whom this was done was able six weeks afterwards to walk up and down stairs with little apparent difficulty, and could run Often the operation brought about a beneficial change in the condition of the patient's bowel · many had been obstinately constipated, the bowel was dilated, and *motions usually had to be stimulated by* an aperient. After ramisection however, daily evacuations took place without such aid

The latest application of the operation, so far as he was aware, was to *Hirschsprung's disease.* Wade of Sydney, had operated upon a boy 10 years old with this condition, who had never had a normal motion enemata *or* aperients always being needed. After leaving hospital he had a normal motion every day without an aperient In such a case the operation differed from that for deformity of a limb in that the rami divided were those going to the inferior mesenteric ganglion, and the operation was done on one side only In America he had been told that no result was obtained from removal of the abdominal sympathetic on one side, but this he thought was because the operators did not go high enough *Experimental* mesenteric ramisection in the goat had resulted in an increase in the normal number of its motions

A boy, aged 16 with congenital spastic paraplegia, had never walked, but tenotomies had been performed on him. His knee was somewhat flexed at the knee After ramisection his first attempts at walking showed the knee still flexed Six months after ramisection he was bowling at cricket, and the film depicted him playing tennis

When he first introduced this operation for spastic paralysis said Mr. Royle, he had the idea that spastic chorea and athetosis were contra-indications, but he had not tried it for those conditions. He now showed films of cases of chorea.

The first was that of a little boy whom he had had under observation for some years The boy had gone to live in another Australian city and had come back four years later with the same degree of spasticity in the hands and intense choreiform movements After operation there was very definite improvement, steady movements could be performed, and the function of the limb was greatly enhanced

A girl, aged 19 with the same condition was unable to sit up unsupported In her the operation restored power of inhibition of voluntary movements by taking *the tone* out of the muscles Four weeks after the operation she was able to open and close her hand well and to grasp objects

A young woman, with spastic diplegia and chorea was able to walk only a few yards After operation she was able to balance and to walk 100 yards

A boy shown had previously had tenotomies done and a fusion operation arthrodesis of the ankle-joint After operation, when the boy had been home a week he was able to walk quite passably, though he had stiff ankles

Mr Royle said that he showed the next picture as an answer to those who stated that the results achieved were due to education or re-education of the musculature This was a child aged 18 months Before the operation the child was unable to use its *right hand* Four weeks after ramisection the child was shown reaching out and grasping objects Another child with a defective left hand showed efficient pronation and supination a few days after the operation

The final case shown was one of post-encephalitic rigidity following encephalitis lethargica

The patient was a man aged 27, who was admitted to hospital in July, 1924. The family history showed no hereditary taint, and as a child he was healthy He gave three years of active service in the war He was quite well until a fortnight before the Christmas of 1923, when he felt weak while at work, and had to go home. After three days in hospital he became unconscious and delirious The delirium lasted four days He was able to leave the hospital a fortnight later, but felt weak in all his limbs, chiefly in the left upper and lower ones He was also very constipated Gradually his condition got worse and his facial expression became more and more fixed. On his admission to hospital speech was slow and monotonous There was no disturbance of sensation. The left upper extremity was held fixed, and was adducted across the chest, and there appeared to be rigidity of the left leg There was a complaint of generalised weakness and stiffness of movement, the latter all being slowly performed though there was no actual paralysis *nor* tremors Knee-jerks were exaggerated, and the plantar reflex was flexor The abdominal and cremasteric reflexes were active The pupils were equal, but reacted sluggishly to light and accommodation. Tests for syphilis, both of blood and cerebro-spinal fluid, were negative When out of bed there was evidence of considerable motor disability. Injections of hyoscine relieved the muscular rigidity within four hours, but in two or three days the effect of this had gradually worn off Saline injections—given to exclude the factor of suggestion—had no influence on the rigidity. In January, 1927, he was strikingly better than before the operation, he was now able to sit erect, and both arms assumed a normal posture, the facies was more mobile and lively, *though there was still* a tendency for the expression to slowly "fade" Movements of both upper extremities were now comparatively free at the proximal joints, though piano-playing movements were poorly carried out The gait also was now active and lively, and he could ascend and descend stairs with little difficulty The bowels were now evacuated daily without help

The invitation of the PRESIDENT to discuss the contribution met with no response. In thanking Mr Royle for his communication Dr. Pugh referred to the untimely death at the age of 26, of his brilliant collaborator Dr Hunter.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.

A MEETING of this Society was held on April 29th, SIR HUMPHRY ROLLESTON, the President, in the chair

DR REDVERS N IRONSIDE opened a discussion on the

Prophylaxis of Neurosyphilis

He dealt first with the efficient treatment of primary syphilis while the Wassermann reaction in the blood was still negative It was known that the nervous system was, or might be affected with greater frequency and at a much earlier stage than was formerly supposed, so that it behoved the neurologist to concern himself not only with established disease and its *treatment*, but *also* with the changes induced in the organism from the time of infection. Eighteen years ago Ehrlich had given the profession a spirochæticide. salvarsan Had there been a decrease since then owing to more efficient treatment of the primary infection in *the* frequency of neurosyphilis? It was rational to believe that the incidence should be less but he held that no definite statement was possible at the present time, for observers were dependent on personal impressions rather than on definite statistical evidence. There were certain indications that neurosyphilis was less frequent, including the evidence given in the statistics of a large insurance company (Metropolitan Life) which, in 1917, showed a rate of 16 6 per 1000 dropping in 1922 to 13 1 per 1000 What he thought could be definitely stated was that syphilis of the nervous system was nowadays seen earlier and was less severe in its manifestations. It was a common*place* among neurologists that patients with late neurosyphilis gave a history of little or no treatment of the primary disease The prophylaxis of neurosyphilis would appear generally to depend on effective destruction of the spirochætes, if possible before the infection had become generalised Efficient management of the primary stages must include thorough physical examination and a study of the cerebro-spinal fluid, Lumbar puncture had great importance in the diagnosis of syphilis per se, it was indispensable as a guide to treatment and to cure or arrest By 1915 it had been shown conclusively that early neurosyphilis could be recognised by special examination of the fluid before secondary symptoms appeared It had become apparent that there was no necessary correlation between symptoms and changes in the spinal fluid, a person with serological evidence of severe neurosyphilis might have no symptoms in his central nervous system, while one with severe symptoms of pathological destruction might have a normal fluid The fact that the spinal fluid might be the sole guide to an otherwise symptomatic and hidden involvement of the central nervous system justified routine use of the test in all cases at the proper time during their course

Turning to the recognition and indications for treatment of latent syphilis, Dr Ironside advised the examination of the cerebro-spinal fluid in all cases of latency Complete examinations should be made biennially over a period of 10 or 15 years, this was a fair compromise with the patient When the cerebro-spinal fluid was normal the case should be left alone—though kept under control—provided the patient had had efficient treatment When the fluid was positive treatment should be given energetically with all the means available The incubation period of clinically manifest neurosyphilis ranged from three months to over 20 years If a graph were made of it, a rise would be seen during the first year owing to acute syphilitic meningitis, meningomyelitis and cerebral syphilis There was a further rise 6 to 11 years later, due to the fact that tabes and general paralysis of the insane had their greatest incidence at this length of time after infection Thus the conception had arisen of acute syphilis of the nervous system, a virulent process, in which the patient's resistance was relatively low, and chronic syphilis of the nervous system characterised by mildness of the early lesions, a long latent period indicating a high degree of resistance of the host, the chronicity of the commoner forms, and the absence of acute constitutional reaction, such as fever

Finally Dr Ironside touched on the problem of the syphilitic parent The Hoffmann rule, which crystallised conservative European opinion, called for three years of treatment with novarsenobenzol and mercury and two years of symptom-free observation before marriage In the light of modern work this would include a repeatedly negative Wassermann reaction in the blood and cerebro-spinal fluid from the end of the first six months of treatment

Discussion.

Dr **PAUL FILDES**, speaking of the early diagnosis of neurosyphilis said that for years it had been known that a large proportion of cases of syphilis in the early stages even before the Wassermann reaction had become positive, had variable degrees of meningitis as was shown by the presence of spirochætes and possibly by a positive Wassermann reaction in the cerebro-spinal fluid The extraordinary thing about these cases of meningitis was that they seldom exhibited any clinical signs of a lesion of the central nervous system, and it was still unknown what was their subsequent fate He knew that 10 or more years ago hundreds of men in the navy underwent lumbar puncture in the primary stage of syphilis Could not some information be forthcoming as to what had happened to them ? He also inquired whether it might not be possible to increase the efficiency of antisyphilitic drugs Salvarsan did not penetrate into the brain, and so could have no action in those cases in which the spirochætes were lying in the parenchymatous tissue of the brain According to some authorities, it was possible to obtain a profusion of antibodies in serum passing through the cerebral capillaries into the brain by the intravenous injection of urotropin at the same time as the antitoxin Certainly there seemed to be some evidence that the permeability of these vessels could be affected by urotropin The difficulty with salvarsan compounds was that they were excessively toxic, and it was possible that some of the severe cerebral reactions that were seen in cases of syphilis of the brain after salvarsan treatment might be due to traces of the salvarsan getting into the brain, owing to the greater permeability of the cerebral capillaries arising out of the inflammation

Mr **DAVID LEES** agreed in emphasising the need for repeated clinical examination of the central nervous system He complained of colleagues in other specialties that they were apt to look lightly on syphilis and neurosyphilis, with the result that disasters sometimes occurred General practitioners also undoubtedly under-treated rather than over-treated these conditions

Colonel **L W HARRISON** laid stress on the necessity for using arsenobenzol in combination either with mercury or bismuth, and giving the two drugs simultaneously The absence of clinically manifest neurosyphilis among thousands of cases treated at his clinic he put down to this combined form of treatment

Dr **WILFRID FOX** referred to the unpleasantness to the patient of the withdrawal of cerebro spinal fluid The whole subject, particularly under the prolonged period of control and frequent re-examination called for, bristled with difficulties

Dr **H M HANSCHELL** referred to some work done upon trypanosome infections, in which the dose of arsenic given by intrathecal injection was regulated according to the weight of the brain and spinal cord of the animal He had applied this principle in treating cases of G P I, and had found that the patient could stand as much as 6 mg of novarsenobenzol placed right into the theca It did not cure the G P I, but it had no adverse effect

Dr **DAVID NABARRO** said that he had had success in the treatment of G P I by intrathecal injection of salvarsanised serum via the cisterna magna

Mr **C H MILLS** was surprised to hear members reverting to intrathecal injections of salvarsanised sera, he thought these had been tested in the past and had been condemned.

Mr **WANSEY BAYLY** did not quite understand why marriage should be advised against for so long a period as three, four, or five years, especially if the wife was treated, as a precautionary measure, during pregnancy He always allowed his patients to marry after a year, and had never known of any unfortunate results

Dr **IRONSIDE** briefly replied on the discussion, which, from the point of view of prognosis and treatment, will be continued at the next meeting

---

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY

AT a meeting of this Society held on May 5th, Dr **E RIVAZ HUNT**, the President, in the chair, Mr **F. E FEILDEN** gave an address on the

Treatment of Urethral Stricture

The condition, he said, is serious, but fortunately not so common as it was a comparatively few years ago For its efficient treatment it is necessary to realise that the bulb, where most strictures occur is the widest portion of the urethra and the external meatus the narrowest Many strictures can be cured permanently by means of a Kollmann's dilator The stricture may be of inflammatory traumatic, or congenital origin, occurring in this order of frequency Those due to gonorrhœa are not uncommonly multiple A single stricture in the penile urethra is rare, and except after operation strictures are seldom found in the prostatic urethra The occurrence of 75 per cent of strictures in the bulb is probably partly because it is the most dependent part of the urethra which causes gonorrhœal discharge to collect in it and partly because the full force of micturition is directed against this part of the canal, so that trauma may be produced, leading to infiltration of the mucosa When the narrowing has progressed sufficiently to cause obstruction the force of the urinary stream increases the chronic inflammatory reaction In support of this view it may be mentioned, said Mr Feilden, that in cases of multiple stricture the narrowest stricture is situated nearest the bladder. Excision should be reserved for cases in which the condition is due to trauma Probably the incidence of stricture could be reduced if every case of gonorrhœa, before being discharged as cured, were submitted to full dilatation

Greater use should be made of the urethroscope continued Mr Feilden, some cases cannot be cured without its aid A gentle hand is most important in passing urethral instruments Unfortunate results are produced not so much by the introduction of organisms as by avoidable trauma of the urethral mucosa Most strictures are amenable to treatment by dilatation As regards silver instruments, the smaller sizes should be avoided, for they are likely to produce false passages Silk-web bougies should be used up to 18, then steel up to 12/15, after which the stricture should be dilated up to 45 Charrière with a Kollmann. In chronic retention, to avoid disaster rapid evacuation of the bladder should never be allowed Strictures ought never to be forced, but some can be rapidly dilated at one sitting Internal urethrotomy is a most satisfactory operation and often no further instrumentation is necessary after internal urethrotomy and full dilatation If there is marked urinary infection or renal insufficiency, drainage of the bladder should precede the urethrotomy In impermeable strictures or those resulting from trauma, Wheelhouse's urethrotomy is the method of choice, and it should be done in all cases of stricture of the bulb associated with periurethritis, periurethral abscess, extravasation of urine, or severe cystitis In elderly patients with recurring epididymitis bilateral vasectomy may be done with advantage A malignant prostate closely resembles a stricture, as there is no residual urine in either case Tabes by producing atony of the bladder may be the cause of an apparent acute or chronic retention The infection behind the stricture must be treated concurrently with the stricture

---

ROYAL MEDICO-CHIRURGICAL SOCIETY OF GLASGOW

A MEETING of this Society was held on April 8th, Dr. J M COWAN, the President, in the chair.

Dr JAMES ADAM read a paper on

Bronchiectasis of Inhalatory Origin

He said that for diagnostic purposes he preferred to inject lipiodol through the glottis after passing a gum-elastic catheter between the cords with the aid of a Jackson laryngoscope This took only a few seconds to put in position With older children and adults it could be done with the patient sitting down, the larynx being cocainised: with young children no anæsthetic was necessary and the patient was supine

After insisting on the need for careful inquiry as to the patient's history and for X ray examination before and after injection of lipiodol, Dr Adam gave his experience of nine cases of bronchiectasis associated with nasal sinusitis and of four post-pneumonic cases The former group entirely or mainly affected the right lung Nasal sinusitis as a cause of bronchiectasis had been entirely overlooked in this country though not in America and bronchiectasis of this origin was preventable by prompt nasal investigation and treatment It was possible, he said that fatal termination of bronchiectasis by cerebral abscess was due to metastasis from the nose as well as from the lung

Dr Adam concluded by giving the results of treatment by nasal operation, bronchoscopic suction, and lavage, and by two-hourly inversion Suction was important at the beginning of treatment; the value of lavage was open to doubt, at any rate in many cases Of the value of systematic inversion there was no doubt whatever.

Prof LEONARD FINDLAY, speaking on the

Ætiology and Diagnosis of Bronchiectasis in Childhood, said that at first sight it might seem one-sided to consider only the condition as met with in children, but it should be remembered that in any large series of examples of chronic pneumonia and bronchiectasis the majority of the patients were children or had apparently developed the disease during childhood. The symptoms were very variable, as he showed by cases in which diagnosis had only been made certain either by intratracheal injection of lipiodol or at autopsy. His experience coincided with that of Armand Delille—that there were three types of cases: (1) cases of bronchiectasis with typical signs and symptoms; (2) cases with suggestive symptoms, but no bronchiectasis; and (3) cases of bronchiectasis with neither signs nor symptoms. Consequently he had no hesitation in saying that not only for the diagnosis of bronchiectasis but also to get correct information about its extent, the injection of lipiodol was essential, and he considered that in pulmonary diagnosis the use of lipiodol was the greatest advance since the introduction of radiology.

Prof Findlay gave an analysis of the signs and symptoms of 25 cases in which the diagnosis was confirmed either during life with lipiodol or at autopsy. As a rule the children were undersized but well nourished Clubbing of the fingers was present in 11 cases, and was related more to the extent of the disease that to its duration Cough was present in 24 and absent in 1. Spit was present in 17 cases and absent in 6; in all of these 6 the disease was of less than 18 months' duration In only 8 cases was the sputum fœtid. Amphoric breathing was audible in 10 cases and whispered pectoriloquy in 7 As in all previously recorded series the left lung was most frequently the seat of the disease; in 16 cases the left lung alone was involved; in 4 the right lung alone, and in 5 both lungs were attacked. In no case was the apex alone the seat of the disease Prof Findlay considered that the disease was caused by, and in fact simply part and parcel of, chronic pneumonia, as had been suggested by Corrigan, though pleural adhesions, to which Hamilton had first drawn attention, also played a part In his post-mortem material both chronic pneumonia and pleural adhesions had invariably been present. The conditions could be traced in all but three of his series of cases to some acute pulmonary disease such as primary broncho-pneumonia, or broncho-pneumonia secondary to the infectious fevers or pleurisy In three cases the condition had set in insidiously

Dr STANLEY GRAHAM dealt with the

Technique of Intrapulmonary Injection of Lipiodol. Lipiodol, he said, was a viscid vegetable oil containing approximately 40 per cent iodine combined with it—not merely in solution Ten years ago, in Sicard's clinique, a patient was receiving intramuscular injections of lipiodol into the buttock for therapeutic purposes and a chance X ray examination revealed the fact that this iodised oil was impervious to the X rays This had led Sicard and Forestier to investigate the possibilities of its use for diagnosis. The iodised oil could be introduced into the trachea either by means of a tube through the glottis (laryngeal syringe or bronchoscope) or by a needle inserted through the cricothyroid membrane. In adults the use of the laryngeal tube might be comparatively simple, but in children, in his experience, it was undoubtedly not the method of choice In a child the glottis was small, and furthermore, it was exceedingly difficult to get the pharynx and larynx sufficiently anæsthetised to permit of the operation The same objections applied, of course, to the use of the bronchoscope in children In adults, good pictures could undoubtedly be obtained, but scarcely, he thought, as good as those obtained when the lipiodol was introduced through the cricothyroid membrane In any case, in children a general anæsthetic was advisable for psychical reasons, apart altogether from the physical discomfort of the operation In older children it was quite possible by means of local anæsthesia to insert the needle into the trachea through the cricothyroid membrane, but the parts were very soft and it was difficult to get the child to avoid any movement or act of swallowing, so that the site of operation might be kept at rest With the child under an anæsthetic, however, it is comparatively easy to enter the trachea through the cricothyroid membrane The needle he had found most satisfactory was one curved and mounted with a flange like a tracheotomy tube The stilette might project beyond the point of the needle when it had a blunt end, just as in an ordinary trocar and cannula, but the form of needle employed in lumbar puncture was better, here the needle was sharpened at an angle of 45° and the stillette similarly angled to become flush with the needle point The size of the needle was of importance It should be large enough to permit of the oil being forced through the lumen

Lipiodol was a very viscid fluid and should be warmed to body temperature as this facilitated its flow through the needle Indeed if this precaution of warming was not taken it would be found impossible to force it through the usual size of needle as shown in the slide, especially when it was curved in the shape of a tracheotomy tube Therefore a syringe which could be heated was to be recommended As great pressure was often needed, a device whereby the piston could be screwed home was convenient

Before administering the anæsthetic, the bronchiectatic cavities should always be emptied as completely as possible by inverting the child and inducing him to cough This was important, for two reasons First, it permitted the more ready and complete filling of the cavities, thus producing a better and more clear-cut picture, and, secondly, it obviated the coughing up of large amounts of sputum during the operation The child being completely anæsthetised, the thyroid cartilage was grasped between finger and thumb of the left hand, the cricothyroid membrane was then identified and the needle inserted in a downward and backward direction With a large needle the operator learnt immediately whether it was in the trachea from the rush of air on withdrawal of the stilette, just as at the introduction of a tracheotomy tube With a smaller needle the lumen was very readily blocked with the purulent secretion in the trachea so that no air could pass It has been found, however, that this point could be readily settled by attaching a syringe and applying suction Where a needle had entered the lumen of the trachea air could be readily withdrawn and also introduced After making sure that the needle was in the trachea, 1–2 c cm of 4 per cent novocaine was introduced to lessen the tendency to cough Then the syringe filled with lipiodol (15–18 c cm) was attached and the oil slowly injected The entrance of the oil might be aided by elevating the shoulders slightly while it was being injected In his experience it was unnecessary to turn the child on its side to facilitate the flow into one or other lung, as the bronchiectatic portions of the lung seemed to have an affinity for the oil, perhaps owing to diminished expiratory efforts and resistance in the affected bronchi Immediately after injection was complete an X ray photograph of the chest was taken, and it was therefore advantageous when possible to carry out the whole procedure in the X ray department; in the case of children an instantaneous apparatus was essential for the production of sharp pictures

It was very important that enough lipiodol should be injected At least 18 c cm were required, and often better results are obtained by giving 30 c cm As a rule, some of the lipiodol was coughed up and swallowed, but enough would remain in the bronchial tree to demonstrate any abnormality

The method was almost free from danger, and Forestier had recently said that he had never seen or heard of any fatal accident Dr Graham himself had seen only two accidents In one of the earlier cases, before the necessity was understood of making absolutely sure that the needle was in the lumen of the trachea (by attaching a syringe and applying suction), some of the lipiodol was injected into the surrounding tissues and could be seen on X ray examination as an opaque irregular mass in the upper part of the chest In the other case the patient (a boy of 3 years) had a violent fit of coughing on recovering from the anæsthetic and a severe subcutaneous emphysema was produced It had been found that this coughing could be controlled to a certain extent by a hypodermic injection of morphia, and this was advisable if it was severe In neither case did the patient receive any permanent danger The subcutaneous emphysema cleared up very quickly, and in the first case the oil would presumably be absorbed through time and the patient was in no way inconvenienced

Although some writers had reported iodism following the use of lipiodol, he had not observed it As much as 30–38 c cm could be given to a child without untoward effects Presumably most of it was coughed up and, at any rate, the absorption of the oil from the site of the bronchiectasis must be very greatly diminished

Discussion

Dr J B MACKENZIE ANDERSON said that his experience of bronchiectasis had been mostly confined to adults, but he agreed with Prof Findlay that the great majority of cases gave a long history and probably started in the early 'teens Most of his patients had been males, the proportion being roughly 5 to 1 An early history was usually obtained of tuberculosis, pneumonia, pleurisy, or empyema Of two cases in elderly people one was associated with a neoplasm and the other with an aneurysm He had no personal experience of lipiodol and was inclined to think that its use was limited, as in most cases the clinical picture was fairly typical and the use of lipiodol unnecessary

Dr W S SYME said that his experience at the Throat and Nose Department of the Western Infirmary and elsewhere suggested to him that there are two quite distinct types of bronchiectasis The first was due to the inhalation of a foreign body Usually one single large cavity was formed, doubtless by ulceration of the wall of a bronchus, as was indicated by the presence of granulations For these the appropriate treatment was lavage of the cavity after removal of the foreign body where it could be found In some of these cases he had no doubt the foreign body was derived from the purulent discharge from an accessory nasal sinus, and often improved considerably when the sinus was treated The second type of case was that referred by physicians In these cases there were usually a number of small cavities and the condition could not suitably be treated by lavage Dr Syme was convinced that disease of sinuses was very often overlooked, especially in children, in whom it was much more common than was generally supposed It should not be too readily concluded that the discharge in a child's nose was due to adenoids A careful examination, if necessary by proof-puncture, which was an easy procedure even in quite young children, would often elicit the presence of antral suppuration

ERRATUM —In our report last week of a discussion on the Medical Aspects of Hæmaturia in the Section of Urology, Royal Society of Medicine, the name of the speaker who immediately preceded Sir Thomas Horder's reply should have been given as Mr Cyril A R Nitch We regret the error

Reviews and Notices of Books.

Surgery of Neoplastic Diseases by Electrothermic Methods

By George A Wyeth, M D With a Foreword by Howard A Kelly, M D Baltimore New York Paul B Hoeber, Inc 1926 Pp 298 $7 50

In this interesting monograph Dr Wyeth gives an account of the electrothermic methods in surgery and describes his own experience in their use for the treatment of neoplastic diseases The electrothermic methods are those in which heat, generated in the tissues by high-frequency oscillatory currents, is used for the excision or destruction of abnormal tissue Of these methods that which is most familiar to workers in this country is the treatment known here as diathermic coagulation or cauterisation. Dr Wyeth describes two other methods In one of these the heat generated by the current is insufficient to coagulate the abnormal tissue, instead, it deprives the latter of water and dries it This method was originally described by Dr W L Clark, of Philadelphia, and named by him "electrodesiccation" It does not seem to have been adopted in this country, although it is widely practised in the United States In the third method an oscillatory current is used to cut tissue and play the part of a scalpel; in addition, the current coagulates the divided surfaces to a slight depth and seals the minute vessels This method has been perfected by Dr Wyeth and practised by him during the past five years The first three chapters deal with the history of the medical uses of high-frequency currents, the production of these currents, and the question of terminology Dr Wyeth prefers the term "endothermy" to surgical diathermy, and he calls diathermic coagulation "bipolar endothermy" Electrodesiccation he prefers to call "monopolar endothermy," because a single (active) electrode is used without an indifferent electrode The use of the oscillatory current for dividing tissue is termed "treatment by the endotherm knife" by Dr Wyeth, the endotherm knife being the active electrode

In the fourth chapter the author describes the principles of monopolar endothermy, indicates its uses, and describes some cases which he has treated by this method In Chapter V the subject of bipolar endothermy (diathermic coagulation) is treated in a similar manner The remaining five chapters, which constitute about three-quarters of the entire book, deal with treatment by the endotherm knife The idea of utilising high-frequency oscillatory currents for cutting tissue did not originate with Dr Wyeth, but he has perfected the method, devised special apparatus for generating the most efficient current for the purpose, and obtained a lengthy experience in its use He employs a single needle as the active electrode (the endotherm knife) and uses it for the excision of malignant and innocent neoplasms of the skin and of the mucous membranes of the upper air passages, rectum, bladder, and female genitalia The amputation of the breast and removal of the axillary glands by its means is described The details of a case of carcinoma mammæ are given; the diagnosis of adenocarcinoma was made by histological examination, and the breast pectoral muscles, and axillary glands were removed by the endotherm knife There was no evidence of shock after the operation and the patient was out of bed on the third day There seems to be little doubt that the employment of the oscillatory current for cutting tissue furnishes the surgeon with additional power especially in the treatment of malignant disease Although it does not stop the escape of blood from the vessels of appreciable size the capillaries and lymphatics are sealed as they are cut Hæmorrhage from larger vessels is stopped by securing the divided ends in pressure forceps and coagulating them by the diathermy current Incisions made by the cutting current heal by first intention, and there appears to be little or no shock after the operation. Dr Howard Kelly, who has written a foreword to the book, has adopted the new method and states that it "bids fair to effect an extensive readjustment of our whole surgical technique" There is much in Dr Wyeth's book that will interest the student of neoplastic disease It is stated that the compilation of cancer statistics and the description of results of treatment are of limited value unless they are accompanied by information regarding the degree of malignancy, derived from histological structure and the degree of differentiation of the cells Four grades of malignancy are described Dr Wyeth speaks highly of the value of electrodesiccation in the treatment of leukoplakia An interesting case of epithelioma of the eyelid treated by the same method is described, ectropion did not occur and there was no recurrence in 18 months

The book is deserving of careful study and the author has conducted original work of no little value. The illustrations are good and the diagrams helpful

High Vacua

By G W C Kaye, O B E, M A, D Sc, F Inst P, Superintendent of the Physics Department the National Laboratory London Longmans, Green and Co, Ltd 1927 Pp 175 10*s* 6*d*

The first five chapters of this book are devoted to a consideration of early types of exhaust pumps and the technique of how to deal with a vacuum when it appears, one chapter being devoted to the question of sealing metals to glass Then comes a section on the modern pumps with their high speed action, good illustrations and descriptions of many types being given A brief chapter is devoted to absorption methods of exhaustion, the best of which is that discovered by Sir James Dewar—namely, the absorption of charcoal at the temperature of liquid air In many cases a good oil pump combined with the charcoal and liquid air absorption gives very speedy action The final chapters are devoted to a description of how high vacua are measured, and how the speed of action of pumps can be determined

The book should prove useful for reference purposes, since the original publications in which the separate inventions are described are nearly always mentioned.

Regional Diagnosis in Brain Affections

Compendium of Regional Diagnosis in Affections of the Brain and Spinal Cord By Robert Bing, Professor in the University of Basle. Third edition, translated from the sixth German edition by F S Arnold, B A, M B, B Ch Oxf. London. William Heinemann (Medical Books), Ltd 1927. Pp 204 15*s*

Dr Robert Bing's compendium is now so well known to English as well as continental students that further recommendation is almost superfluous On various occasions we have reviewed it in these columns, and need therefore say no more than that this third English edition can be put with confidence into the hands alike of student and practitioner, it embodies in readily assimilable form present-day teaching in regard to neurological diagnosis The basis of clinical neurology is the anatomy and physiology of the nervous system, without which the study of nervous disease is vain and at the same time uninteresting With it, cases become illuminated and therapy less empirical If this introduction is utilised as it deserves to be it cannot fail to provide the physician with a working knowledge of neural mechanisms in health and disease that he can apply to clinical practice with advantage to himself and correspondingly to his patients The clarity and simplicity of the numerous diagrams enhance the value of the text Incidentally, we note that the German legends in some of the illustrations have undergone translation, but not in all

WALL-MAPS OF THE C N S

Bilder zur makroskopischen Anatomie des Gehirns und zum Bahnenverlauf; Erlauterungen zur 2 Auflage der Icones Neurologicæ By V. STRUMPELL und JAKOB Edited anew by FRIEDRICH MULLER and HUGO SPATZ, Munich With 45 illustrations Munich J F. Lehmanns 1927

WE have received a new series of the Icones Neurologicæ or wall-maps of the central nervous system, designed for teaching purposes in schools of anatomy and neurology A small explanatory brochure accompanies them, with reproductions of the maps on a much reduced scale and appropriate textual explanations The wall-maps are admirable alike for their relative simplicity and for the distinctiveness of their colourings, and as far as we have noted critically their accuracy is unimpeachable The terminology, as is just, is Latin Any teaching school possessing these Icones can congratulate itself on a labour-saving acquisition of a most valuable kind.

CHILD WELFARE

The Health of the Child of School Age By Various Authors With a foreword by SIR THOMAS OLIVER, M D, F R C P London Humphrey Milford, Oxford University Press. 1927 Pp 204 6s

THIS book consists of a series of 10 lectures recently delivered to the public at the Institute of Hygiene All the writers are authorities on the subject with which they deal, and the lectures, taken together, form a valuable introduction to the problems of school children's health To mention a few chapters only, the prevention of nervous disorders is discussed by Dr Risien Russell, Dr L R Lempriere deals in a most scientific and convincing manner with the dietetic problems of a school, and Dr C E Shelly brings out many points of interest on the incidence of infectious disease The other articles maintain their interest throughout, and the book should be of real benefit to parents and to schoolmasters, particularly in enabling the former to obtain a sympathetic understanding of the difficulties with which the headmasters are often confronted

Nutrition Work with Children By LYDIA J ROBERTS, Assistant Professor of Home Economics, University of Chicago University of Chicago Press 1927 Pp 394 17s 6d

THIS book gives an account of the theoretical and statistical aspects of nutrition in childhood, and of the work which has been done in American schools in investigating malnutrition and in educating the public on this subject Various methods of measurement and standardisation are discussed, and a description of the Pirquet system is given It will probably appear to the medical reader that the influence of alimentation on the body-weight is over-estimated, while that of endocrine activity is entirely neglected An interesting account is given of attempts which have been made to educate school-children in the selection of their own diets As applied to normal children, the methods employed should be of considerable value, but it is doubtful whether cases of true malnutrition are best dealt with by so uniform a régime, and whether the author's enthusiasm for increasing the milk allowance of *all* these children is not misplaced

JOURNALS

THE JOURNAL OF INDUSTRIAL HYGIENE for April contains two articles of some moment In the first Dr W Watkins-Pitchford deals with silicosis as seen among gold miners and changes produced in it by legislative and administrative efforts, summarising his work at Johannesburg over many years Silicosis is the name now given to miners' phthisis as indicative of the origin of the disease which also attacks other workers exposed to silica dust such as stonemasons metal grinders and potters; it will also attack the ordinary population in a country of dust storms composed of silica particles Dangerous particles of silica dust vary in size from 0 25 to 10 microns, larger or smaller particles are not phagocytosed by macrophage cells, which also engulf tubercle bacilli Silica dust causes fibrosis in the lungs, which condition may lie latent for some years to be precipitated by an infection Shortness of breath and a tendency to obesity indicate the inception of silicosis, which, by itself, is seldom serious Pulmonary tuberculosis and silicosis are intimately related one helping the other, and when associated are far more fatal than either alone Pigmentation of the lungs always accompanies silicosis and precedes the formation of grey fibrous tissue in nodules The presence of fibrous nodules can be detected by radiography, which is more accurate than clinical examination When tuberculosis is superadded, the heart shadow takes on the asthenic or vertical type The average time for simple silicosis to develop in a Rand miner is now about 10 years, which is longer than before steps were taken to minimise the dust hazard and is inversely proportional to the intensity of exposure to silica dust Great necessity exists for more rigid exclusion from underground of all possible sources of tuberculous infection, to day native labour supplies such a possible source Natives when employed as long as Europeans exhibit the same tendency to develop silicosis but are far more prone to acquire simple tuberculosis Three stages in the disease, ante-primary, primary, and secondary, are recognised for compensation purposes, according to the presence of impaired capacity for work and of tuberculous infection The precautions adopted by mechanical means to suppress the dust hazard and by medical means to exclude the predisposed and early cases are described, and the favourable results attained are explained The struggle against miners' phthisis on the Rand as here told makes an interesting story —In the second article Dr W I Urquhart reports a series of experiments on animals to ascertain how death is produced by electric shock Apparently death may be due to primary cardiac failure, or to primary respiratory failure, or to a combination of both The current applied to the brain causes, by intense stimulation, generalised muscular contraction, when it is broken, a condition of profound paralysis or block follows in the respiratory, vagus, and vasomotor centres No histological destructive changes are associated with the block, which may pass off if life is maintained by effective artificial respiration until reflexes and the normal rhythmic discharge of respiratory impulses return Much, however, depends upon whether gross damage has been done to the brain or spinal cord by charring at the point of application of the electrodes The conclusion is drawn that, in cases of unconsciousness after electric shock, artificial respiration should be continued until there is evidence of death in cooling of the body or in the onset of rigor mortis

Reports and Analytical Records.

BOTTLED PALE ALE

(MATTHEW BROWN AND CO, LTD, THE BREWERY, PRESTON)

THIS ale was remarkably brilliant, free from any deposit, and the condition and palate left nothing to be desired The brewing operations obviously had been carried out on sound lines and before being bottled the beer was filtered and carbonated On analysis the following results were obtained —

Specific gravity of wort before fermentation		1045 4°
Present specific gravity		1008°
Alcohol by volume		4 8 per cent.
Extractives (total soluble matter)		3 83 "
Consisting of	Mineral matter	0 32 "
	Protein	0 30 "
	Carbohydrates, &c	3 12 "
Acidity as acetic acid		0 11 "

The ale is free from added sulphurous acid and other preservatives

HE LANCET.

DON: SATURDAY, MAY 14, 1927

MPLOYMENT OF MARRIED WOMEN

Married Women (Employment) Bill. which an untimely end in the House of Commons 20th, was of interest to the medical profession least two direct points of view. It concerned number of medical women now engaged in ent and municipal service on contracts rminate automatically with marriage, and, the arguments which secured its rejection nly of a medical character Both the mover nder of the motion for rejection made great h the disabilities of pregnancy which they l to consider not only the natural, but the le result of marriage One speaker even that "in normal cases a woman was not ent a few years after marriage as before," nded us portentously that the sexes were not all respects The Government spokesman, NALD MCNEILL, elaborated the same point, nplained that supporters of the Bill were ng "enormously" the sickness risk and the discontinuance of service by employing women, with a corresponding "immense efficiency The one medical speaker in the Dr GRAHAM LITTLE, found himself unable rt these gloomy prognostications and, stating new of no medical authority for the arguments ld the House that the universities of this had found it perfectly practicable to make nction whatever between the sexes in the of marriage But he implied and correctly, a concerning the sickness-rates of married as compared with single women and men under similar conditions, are very hard to

days when the largest educational authority orld gave women teachers the free choice ing after marriage,[1] it was found that the of days absence for married women was num, as against 8 2 for single women and en It may be noted that the differential st married women was found exclusively er and upper extremes of age, for between 5 years of age married women actually s absence than single As for interruptions gnancy, the last census revealed that the mber of children in the professional man's 0 98 The married woman Civil servant contribute double her quota of disability nously dislocating the work of a well-epartment The bogy of the woman official l by recurrent pregnancies and a "lot of n" need not be taken too seriously It was teaching profession that very few women than two children attempted to remain d medical women in a similar situation ave up practice, at any rate, until the at school Mothers are at least as aware ue to young children as are Members of Parliament Even if it could be established that a substantially greater sickness risk has to be debited against the married women, it by no means follows that the last word has been said on the efficiency of the woman as worker Marriage has been described as a "battlefield"; it is certainly an education, and anyone can imagine that this education may often be an asset This is especially true of positions where the woman official has to deal with other wives and mothers in some educational capacity, either as a teacher or in the public health service Working women not unnaturally prefer to deal with one of their own status on matters affecting married life, and they listen more readily to advice in respect of children from a woman who has, or who might have had, children of her own Such an attitude on the part of a large proportion of the public is not a negligible factor in the conduct of great services which ultimately depend for their success on the coöperation of the public It may further be argued that working mothers are not the only persons who would benefit if the atmosphere of some schools and departments staffed by single women, which tends to be too spinsterish, were mitigated by a leavening of the mated.

The point of view of the woman herself was well put in the debate by Mr. PETHICK-LAWRENCE He spoke feelingly of the sad waste entailed on both sides when an expensively trained and experienced officer suddenly found herself thrown out of employment and deprived of pension rights just at the time when the most valuable earning period of her career was beginning This is an aspect which closely concerns medical men who have given their daughters a costly education for which they and the community are entitled to expect some return Recently the Durham County Council has dismissed a woman medical officer, appointed last August, on the sole ground that she has since married. no question of resignation on marriage having arisen at the time of her appointment This sort of prophylaxis against possible inefficiency can hardly be defended In other departments of life a married woman is now at liberty to use her gifts in any manner she and her husband please, and (as Sir HENRY SLESSER suggested) it is difficult to see why the established services should remain the one exception When the matter next comes before the House it is to be hoped that broader and more scientific views will prevail.

◆

THE ENDOTHERM KNIFE

BLOODLESS surgery was the expression formerly applied to the manipulation of bones and joints under anæsthesia, no incision being made in the skin. The term has made a wide appeal to the public, whose dread of "the knife" is largely due to an imaginary picture of an operating theatre, based on observation of the mass of blood that may well or spurt from a single accidental cut It practice the amount of blood lost by the patient under a modern surgical team is surprisingly small, and if primary hæmorrhage under these conditions does the patient any harm it is only by prolonging the period of anæsthesia For even with the most efficient swabbing and clamping the surgeon's field of vision may be temporarily obscured by oozing. and if hæmatomata are to be avoided the time spent in ligaturing small vessels is not negligible For these reasons alone a technique promising a bloodless field of operation is to be welcomed, if, as is claimed by its exponents, it has also other signal advantages, such as the promotion of healing by first intention, and the sealing of lymphatics and very small vessels in the very act of incision, it certainly deserves the attention of surgeons The technique to which we refer is the alternate use through the same electrode —a needle mounted on a hard rubber or fibre handle, known as the endotherm knife (G Wyeth) or the acusector (H A Kelly)—of an undamped high-frequency (H F) current for division of the tissues, and a damped H F current to secure hæmostasis of the larger vessels

---

[1] Sickness Data of Elementary School Teachers
-19 Journal of the Royal Statistical Society,

A brief excursion into nomenclature is desirable if the relation between these methods and the older electro-cautery is to be understood At present the word diathermy is often used indiscriminately to indicate medical diathermy, where the aim is to warm the tissues to a point short of destruction, or surgical diathermy, which includes the various methods of adapting the high-frequency current to disintegrate or destroy animal tissue These methods, whereby heat is generated within the tissues in response to the oscillations of a H F current, differ radically from the transmitted heat given out by the electric or galvano-cautery, the Paquelin cautery, and the Percy cautery The effect of the transmitted heat is to cauterise or burn the tissues, the heat being generated in the applicators which are hot when applied The sharp pointed active electrode carrying H F current, on the other hand, is always cold when applied, and the heat generated in the tissues themselves does not char or burn It can, however, be used to destroy by desiccation, to destroy by coagulation, or to incise by cellular disintegration Dr G Wyeth, in a book which we review on another page, suggests that the term diathermy shall in future be used only in the sense of medical diathermy, while the term endothermy (heat from within) shall be used to include (1) monopolar H F used for desiccation , (2) bipolar H F , used for coagulation , and (3) the endotherm knife, being a H F oscillatory current produced by means of a triode which, when making contact with the tissues through a mounted needle, produces a cutting effect, sealing lymphatics as it cuts The method of electro-desiccation is applicable to a wide range of superficial lesions, including malignant ones which do not involve the deep tissues, and also warts, moles, nævi, and pigmented areas Dr W L Clark first described the technique as long ago as 1911[1] He started from the axiom that since the effect of heat on animal tissues ranges from simple hyperæmia to charring, there must be between those extremes a point where desiccation of the tissues would take place His idea was to produce, control, and sustain a degree of heat sufficient to cause a rapid desiccation of the part to be treated, sterilising it and converting it into an inert mass His experiments on cakes of soap—drying a marked area to pulverising point without charring or discolouring the paper in which it was wrapped, and without drying the soap in the surrounding areas—led to others on potatoes and on raw liver, and, finally, to a successful use of the monopolar damped H F current on superficial lesions in human subjects For deeper lesions bipolar endothermy may be used , the heat is generated by connecting one pole of the apparatus to a wet, indifferent electrode under the patient's buttocks, the operator making contact with the active electrode The d'Arsonval current used is of comparatively low-voltage and high amperage—200 to 3000 milliamperes—and a deep penetrating coagulation results It is claimed that secondary hæmorrhages rarely occur in experienced hands, but operators working near a large vessel are advised to ligature it in advance

The third type of endothermy, using Dr Wyeth's classification, is the one to which we wish to draw special attention H A Kelly and G E Ward[2] report excellent results in the surgery of carcinoma of the breast from the use of the endotherm knife devised by Dr. Wyeth This is not a true knife, but a current operating through the same type of needle as is employed for the application of bipolar damped high frequency currents The underlying principle of its action is the application of undamped high frequency current, which causes a cellular disintegration of the tissue at the point of contact, an arc being formed between the tissue and the tip of the needle which is held just over it This introduces a new technique which is not easy to acquire, the impulse to make some pressure, as in using the scalpel, being difficult to resist The exponents of this technique claim that there is healing by first intention, an immediate closure of lymphatics, capillaries, and small blood-vessels, and a diminution in the risk of local recurrence The number of clamps and ligatures necessary during an operation is considerably reduced and in some cases may be entirely eliminated, for in order to seal the larger blood vessels, which are clamped in the usual manner, the current is switched over to damped high frequency and a short application made to the clamp controlling the vessel The measure of the duration and amount of the current to be applied is a slight ring of coagulation at the point of the clamp This procedure is said to be quicker and just as efficient in stopping hæmorrhage as is the tying of a ligature Kelly and Ward warn the surgeon that the current used in the endotherm knife, which they prefer to call the acusector, causes muscular contractions when applied to nerves or muscles, but such contractions can be made almost negligible by reducing voltage according to directions given The coagulating current must also be used with the utmost caution near a muscle The great advantage of the combined use of the two forms of current is that, since so few ligatures are required, the operator need hardly ever touch the wound with his hands The necessity for having coagulation high frequency current at hand during the operation led Dr Wyeth to design the endotherm,[3] an instrument equipped for the production of currents used in monopolar and bipolar endothermy and in operations with the endotherm knife The undamped high-frequency oscillations are developed by means of a triode oscillation, the grid and anode circuits being coupled together and timed to a frequency of approximately 1000 kilocycles Very few details of the undamped high-frequency apparatus are set out in Dr Wyeth's original description of the apparatus or in his book, a disappointing omission since doubtless many surgeons will be anxious to investigate the possibilities of the combined method without having to instal an expensive complete equipment when their existing damped high frequency apparatus could be modified and extended to function for the use of the endotherm knife In this connexion it may be noted that an error has crept into the diagram of the electrical connexions of the triode oscillation found on p 30 in Dr Wyeth's book, if followed out it would lead to a considerable display of fireworks The success which has already attended the use of the endotherm knife in certain operations leads us to hope that further investigations will be carried out in this country There is especial need for the correlation of the wave form of the high-frequency oscillations and the resulting changes produced in the various types of tissue cells Apart from the destruction of neoplastic growth, the desirability is obvious of pursuing investigations into a technique by which no drop of blood is spilled "Prepare thee to cut off the flesh," said Portia, "Shed thou no blood" It would seem that we are approaching an era of surgery when Portia's dictum will not be accepted as a conclusive argument

BRONCHIECTASIS

The discussion on bronchiectasis at the Royal Medico Chirurgical Society of Glasgow reported in another column illuminates a number of issues upon which physicians and pathologists alike are still in doubt Sometimes we may feel inclined to wonder if our knowledge of this obstinate and unpleasant disease is advancing at all The treatment of the malady has certainly not made rapid strides, and the new major operations of surgery—thoracoplasty, and the like—have not been attended with that measure of success which has been noted in similar operations for pulmonary tuberculosis Perhaps such success was hardly to be expected The disease is usually far advanced when the patient reaches the surgeon and the whole field of operation is saturated with the organisms of suppuration from which the numerous pleural adhesions are generally not exempt It is clear, therefore, that if radical measures are to be adopted earlier diagnosis is essential, and along this line, at any rate, some advance has been made with the introduction of lipiodol The technique of this diagnostic measure is safe and easy, and there is reason to believe that the employment of the substance will go far to increase the value of diagnosis It presupposes, of course, the possession of an up-to date X ray plant and a skilled technician to use it, and like so many of the modern diagnostic methods, it adds yet another demand for increased facilities for the institutional diagnosis and treatment of disease But even with this addition to our armamentarium we are still faced with many problems in the causation of bronchiectasis At the discussion in Glasgow Dr **James Adam** mentioned the cases traceable to nasal sinusitis, a group not generally recognised in this country though described in American literature, whilst Prof **Leonard Findlay**, quoting Prof **Armand Delille** in support, emphasised the difficulties of those cases in childhood which had symptoms but no signs, or even a complete absence of either There is abundant evidence, indeed, for recognising non-tuberculous fibrosis of lung in childhood as the starting-point for many of these cases, and physicians who work in chest hospitals not infrequently have the mortification of watching cases of fibrosis of lung in children slowly going downhill from fibrosis to bronchiectasis without any clear line of demarcation and without being able to call a halt in the disease It seems unjustifiable to resort to drastic surgical measures as long as the condition is merely one of fibrosis and once sepsis—in other words bronchiectasis—has become established surgical aid may well be too late Probably, however, only a certain proportion of these cases of fibrosis go on to bronchiectasis, and it would be a great boon if we knew definitely what was the deciding factor Meanwhile it is essential not to confuse the cases with pulmonary tuberculosis, but to watch carefully for the insidious onset of any signs of pulmonary sepsis which undoubtedly spell bronchiectasis Children can be taught not to swallow their sputum, and the frequent bacteriological examination of their expectoration should never be neglected In the late stages the onset of lardaceous disease seems to be a landmark in the slow progress of disease not infrequently overlooked, frequent examinations of the urine would appear to be just as important as sputum tests On the morbid anatomy side of the picture we are inclined to think that the frequency of cerebral abscess as a complication of bronchiectasis has been exaggerated Of much more importance is the frequency with which a full bronchiectatic cavity is mistaken for an empyema, often with disastrous surgical results The histological picture of bronchiectasis, too, is essentially disappointing By the time these long standing cases reach the post-mortem room all hope of elucidating any satisfactory information as to causation has long since passed In conclusion, therefore, we have frankly to acknowledge that although there are some recent signs of advance in knowledge, notably in the matter of lipiodol, the condition of bronchiectasis has not been a conspicuous example of the advance of modern medicine, especially as regards the purely medical group of cases That the purely surgical variety of the disease, associated with a traumatic factor or foreign body, is a separate entity requiring separate consideration was well brought out in the Glasgow discussion.

JOHN LYDEKKER

A small book written by Mr W R Dawson and published by the Seamen's Hospital Society tells the story of a great hospital benefactor John Lydekker, merchant of London and shipowner (1778–1831), had almost as great an influence on this Society as would entitle him to the prayers usual on behalf of a pious founder His father left New York when it ceased to be an English colony and brought his children to London Here the eldest son was at one time an eminent physician, and the third son, John, became a merchant in Cheapside, concerning himself mainly with cane and whalebone, then wanted for corsets and the ribs of umbrellas Naturally he took an interest in whaling ships in the South Seas, and he owned four in 1829 In 1830 he made a handsome donation to the Seamen's Hospital in recognition of their kindness to some Polynesian seamen from his ships In those days, less than a hundred years ago, life in London was much less secure than now, water was often drawn from shallow, contaminated wells, drainage was by open sewers to the Thames, burials were apt to be made in the crypts of churches to avoid the resurrectionists In July, 1832, Lydekker went from his house in the Strand to stay with a friend in Fenchurch-street, fell sick of cholera which was then prevalent, and feeling himself near his end, wrote out a short will which he signed, leaving the residue of his property to the Seamen's Hospital Society This will, although unwitnessed, was not contested by his family, and brought the Society a sum of £58,729 At that time the Seamen's Hospital was situated in the 104-gun ship *Dreadnought* lying in the Thames off Greenwich, but in 1870 a 99-year lease of the old infirmary of Greenwich Hospital was acquired, and in 1926, with the help of the Lydekker bequest, £23,000 left by B T *Crichton*, and other benefactions, patients to the number of 28 264 were treated in one or other of its eight *establishments* The Seamen's Society owes many of its opportunities of usefulness to the munificence of shipowners, of whom Lydekker was the most bountiful There is a marble monument to his memory at Lloyds and a stained glass window in the chapel at Greenwich

"Ne quid nimis"

THE DEVELOPMENT OF MENTAL HOSPITALS

CIRCULARS have been sent out by the Royal Medico-Psychological Association to every mental institution in England inviting the medical superintendents to afford to their staffs facilities for attending clinical meetings in accordance with a plan whose organisation is now under consideration. It is proposed that these meetings should be held under the auspices of the Association, and to encourage the attendance of the workers in psychiatric establishments the managing bodies will be asked to sanction travelling and other reasonable expenses to their medical officers. The movement is in accordance with the expressed wishes of the Boards of Control in England and Wales, and in Scotland. The circular suggests that the clinical meetings should not be limited to members of the Association, but that all medical men, institutional officers, or private practitioners should be made welcome and there can be no doubt whatever of the value of such a departure. Such meetings would stimulate psychiatric work and further the better treatment of cases of mental disorder to the benefit of the patients and to the instruction of the profession in directions of particular value for the conduct of practice. A memorandum on the subject issued by the Association expresses the hope that there may be 12 meetings a year in each of certain areas whose size remains for decision, and that a special point at these meetings should be made of the study of groups of cases presenting similar symptoms. All will agree with the implication that the demonstration of actual cases at clinical meetings is more instructive than the reading of papers, and the scheme does not depend for success upon securing large attendances; small gatherings at which interchanges of personal experience can take place should give better results than crowded meetings. The existing plan of the Association will need dividing into areas in accordance with the number and situation of the mental hospitals, but the actual scheme has not yet been formulated, and for pecuniary reasons the support of the local authorities will be required, for it is unreasonable to expect the medical staffs of the institutions to finance a great education design as well as provide for its scientific and practical working. The most valuable result of such a scheme would be the relief from isolation of many medical institutions. Mental hospitals lack public sympathy and support, and fall easy victims to misrepresentation because much of their work is necessarily isolated. But though they can never be entirely open institutions, it is quite misleading to describe the insane as being treated "behind shut doors." This is well shown in an impressive plea for the fuller cooperation of the public in the life of psychiatric institutions written by the President of the Royal Medico-Psychological Association in aid of the National Council for Mental Hygiene.[1] Lieut.-Colonel J. R. Lord points to the good results which would follow upon the appointment of independent, unofficial and voluntary mental hospital visitors as an intermediary between patients and their homes, and all who have studied the problems concerned will agree with him that an organisation of such visitors would be a powerful agency both for science and humanity.

KRUKENBERG TUMOURS

AT a recent meeting of the North of England Obstetrical Society Prof. Blair Bell who showed three cases of Krukenberg tumour in women aged 35, 42 and 32 remarked that these tumours which were originally described by Krukenberg as primary sarcoma carcinomatodes of the ovary, were now invariably regarded as secondary to gastric or possibly intestinal carcinoma, as was exemplified in his own cases. Similar views are expressed by Dr. Julius Jarcho,[1] attending gynæcologist and obstetrician to the Sydenham Hospital, New York City, who records seven cases which he had studied at the Szent Istvan Hospital, Budapest. Three of his patients were operated on for tumours of the adnexa, the material removed showing metastatic ovarian tumours. In two of the three the necropsy revealed gastric carcinoma, while the third patient was lost sight of. In the four remaining cases the ovarian tumours were not discovered until the necropsy, and like the other two were found associated with primary gastric carcinoma. Of the four gastric carcinomata in which a histological examination was made three consisted of solid groups of epithelial cells, some of which showed mucinous changes, while one carcinoma was fibrous and showed no mucinous transformation. On naked-eye examination the ovaries in all the cases showed typical uniform enlargement with preservation of the normal shape. The cut surface was generally solid, except for a few discrete cysts. In some areas the solid tissue appeared gelatinous. Histologically, the tumours presented the usual Krukenberg structure, signet-ring cells being arranged loosely or compactly between connective tissue rich in spindle-shaped cells. Two of the ovarian tumours showed irregular gland-like structures resembling adenocarcinoma but in transition, with groups of signet-ring cells. Evidence was found that the gastric carcinoma had been propagated by retroperitoneal lymphatic channels. Dr. Jarcho comes to the conclusion that, in the formation of these ovarian tumours, propagation through the lymphatics plays an important part, whereas propagation along the blood-vessels and implantation are of decidedly less moment.

FOOD HANDLERS

SHORTLY after the war, when new sanitary regulations were being issued,[2] the opportunity was taken to include measures to prevent the spread of infection through the handling of food by persons carrying the germs of dysentery and enteric fever. More recent regulations[3] require that no person who is aware that he is suffering from tuberculosis of the respiratory tract shall take up employment in connexion with a dairy which would involve the milking of cows, the treatment of milk, or the handling of vessels used for containing milk; they also give the local authority power to secure the dismissal of any such person already employed if he is in an infectious state. It has been suggested that much could be done towards achieving the object of these latter regulations if employers in the milk trade, before engaging an employee, required the production of a recent medical certificate stating that the physical condition of the applicant for employment was such as to satisfy the requirements. Some local authorities have accordingly made arrangements for the necessary examination to be made free of charge by their tuberculosis officers. The medical examination of food handlers has been taken very much further in the United States of America, where Dr. M. James Fine, Director of the Tuberculosis Division, Newark City Department of Health, New Jersey, has recently reported[4] on the examinations of food handlers conducted in that city of about half a million inhabitants. The work was started with restaurant employees, and has gradually extended, until at the present time grocers, confectioners, delicatessen-store workers, and milk handlers are examined. Owing to the absence of positive results the routine examination of nose and throat cultures was discontinued in 1926; cultures are only made w if considered necessary after the examination the throat Widal tests for typhoid fever have ›n discontinued for the same reason The figures en relate to the years 1920-25, during which ,188 restaurant employees and 9869 milk dealers were amined, of all those examined, 155 were rejected y the health department for tuberculosis, and 45 for venereal disease Temporary cards were issued to 95 persons who had tuberculosis or venereal disease, but whose condition was not active Although the examination is compulsory, probably those food handlers who came to the diagnostic clinic were persons who felt reasonably certain that they were free from the evidence of communicable diseases, this self-selection undoubtedly had some influence in keeping down the percentage of tuberculous and venereal diseased individuals among those examined Considerable stress is laid upon the importance of the examination being made by physicians specially ppointed to do this work, obviously it relieves the vate doctor of the responsibility of taking away his ent's employment Dr Fine comments upon the number of food handlers rejected by private rs in Newark, Kansas City, and New York City vaik itself there have been fewer rejections each ce 1920, this may be taken as an indication ersons with tuberculosis or venereal disease t they will not be certified fit for employ- od handlers, they secure other occupations concludes his interesting survey by ig the arrangements made for the examina- od handlers in other countries, which he inadequate

ION AND DEATH CERTIFICATION

AR letter will be addressed shortly to he medical profession by the Cremation Society of England, signed by the Chairman of the Society, Prof Chalmers Mitchell, Sir Thomas Horder, and Mr Herbert T Herring, honorary secretary of the Society, in which it is pointed out that certain reforms are necessary in the interests of the medical profession as well as of the public in respect to the disposal of bodies by cremation The Births and Deaths Registration Act, 1926, comes into force next July, and imposes upon the medical practitioner important public duties, without remuneration in the case of burial, but in the case of cremation procedure is controlled by separate regulations These regulations, which are laid down by statutory rules and orders under the Cremation Act, 1902, enact (under Form B) that the body must be seen and identified after death, and the fact of death certified by the registered medical practitioner who attended deceased in the last illness and who can certify the cause of death This service is remunerated as a rule with the fee for an ordinary professional visit But in disposal of the body by cremation a second medical certificate (under Form C) must be given, in which the identity of the deceased, the fact of death, and other particulars—verifying the answers set out in Form B—must be given either by an independent medical practitioner, of not less than five years' standing, who has been appointed by the cremation authority for the purpose, or, if such an appointment is not made by a practitioner of five years' standing who holds one of the following appointments medical officer of health, police surgeon, certifying surgeon under the Factory and Workshop Act 1901 medical referee under the Workmen's Compensation Act or who is physician or surgeon to a public general hospital containing not less than 50 beds It is to the circumstances connected with Form C that the circular letter refers, pointing out that the medical man signing it ought to receive fair remuneration The Cremation Act requires the form to be signed by medical practitioners of five years' standing either appointed by a cremation authority or being the holders of certain public appointments and the Cremation Society desires to bring before the medical profession the necessity of increasing the opportunities of the cremation authorities to use their power of appointment Cremation is slowly becoming more frequent in this country, where it has always been advocated by an influential section of the medical profession, so that it is reasonable for the Society to invite the attention of general practitioners to their opportunity of collaboration The remuneration suggested by the Society for certificates under Form C is "the usual fee for a first professional visit," and the direct object of the circular letter is to invite doctors to communicate with the Cremation Society and signify willingness in such circumstances to sign these confirmatory medical certificates required by the Cremation Act Lists can then be furnished to the cremation authorities, who will know where to turn in making their appointments, and who will be expected to recognise the responsibility incurred, and to make their selections accordingly

PULMONARY INFECTION FOLLOWING OPERATION

IT is not always realised how useful is a patient's ability to cough, and thus expel infective material from the lungs and bronchi If (as is said) there is always some inhalation of septic secretions during anæsthesia, then a patient's liability to post-operative pneumonia depends on the degree to which his power of coughing is conserved An estimate of this power might therefore be some guide to whether there was a likelihood of his contracting the complication Such an estimate is not impossible, for the efficiency of a cough depends on the depth of the initial inspiration and the force behind the succeeding expiratory effort—which is derived almost entirely from the abdominal muscles—and it is just these two factors that are estimated by measuring the vital capacity, that is to say, the maximal amount of air that can be breathed out after the deepest possible inspiration This essentially is the argument which forms the basis of a recent paper [1] by Dr E D Churchill and Dr Donald McNeil, of Boston They found that after operations on the right upper quadrant of the abdomen the patient's vital capacity was on the average reduced by 70 per cent on the first day, after which a steady improvement took place, until on the fourteenth day the reduction was only 20 per cent After clean appendicectomies and operation for uncomplicated inguinal herniæ, there was a fall of 50 per cent on the first day, and a normal figure was obtained by the eleventh day, after non-abdominal operations no reduction was observed This diminution in vital capacity is attributed mainly to the abdominal muscles being held in voluntary or involuntary spasm, so as to protect the injured part from painful movement, and also in part to inspiration being restricted by a tight abdominal binder, in a normal individual such a binder was found to reduce the vital capacity by 30 per cent Other less important factors were posture, the effect of sedative drugs, and abdominal distension In support of their findings, Dr Churchill and Dr McNeil quote figures given by E C Cutler and A M Hunt,[2] with whose results their measurements closely correspond They reach the general conclusion that the chances of pulmonary complications increase as the patient's preoperative vital capacity approaches his theoretical tidal air requirement, but the evidence they give is insufficient for proof Cases of cardiac and pulmonary disease were excluded from the series, and the height and weight of patients, though they were observed, are not recorded The results of the investigation are what might be anticipated A tight abdominal binder clearly limits both costal and diaphragmatic inspiration, and a full expiration is obviously impossible when the abdominal muscles have recently been incised Other things being equal, the postoperative variations observed are probably due to variation in the stoicism of the patients Postoperative pneumonia notoriously attacks the bases of the lungs, which are expanded almost entirely by diaphragmatic action Any contraction of the diaphragm must either raise the intra-abdominal pressure or move the abdominal wall, and either alternative will cause pain in an abdominal incision When this pain is present, movement of the diaphragm is repressed, the bases of the lungs are poorly aerated, and secretions stagnate in them, for even a cough cannot clear a portion of lung containing too little air If this is the real reason why inflammation so often attacks the bases of the lungs after abdominal operations, the upset of balance between costal and diaphragmatic respiration is a greater danger than limitation of the power of coughing It seems doubtful whether preoperative estimation of a patient's vital capacity will ever prove a valuable method of judging his liability to this complication

EARLY INFANT MORTALITY

IN a recent number of the U S Public Health Reports (March 18th, 1927) Dr E Blanche Sterling, an acting assistant surgeon in the Public Health Service, presents an exhaustive statistical study of the problem of fœtal and neonatal death The subject is one of great moment in the United States of America, for Dr Sterling opens her study by showing that the returns for dead births and neonatal deaths during 1924 account for 70 7 per cent of the whole number of infant deaths in the States where precise figures are available And, as in other countries, the neonatal death-rate in the States has not fallen at the same rate as the infant mortality-rate Dr Sterling brings forward evidence to show that clinical examination alone cannot be relied on to elicit the true cause of fœtal death , in many instances a post-mortem examination is needed to reveal it Among a total of 18,634 registered dead births, in 30 2 per cent the cause is entered under the heading " not specified or unknown," while the complications of labour, including dead births due to trouble with the umbilical cord, account for another 23 per cent The total figures, it may be noticed in passing, include " miscarriages and abortions," and if these were omitted the percentages would presumably be still higher In an analysis of deaths based upon autopsy the percentage of deaths from unknown cause—that is, after elimination of every ascertainable cause,—drops to 8–10 per cent , and those ascribed to complications of labour rise to 35–50 per cent Many of the latter are due to intracranial lesions discoverable only by opening the skull The proportion is, roughly, the same whether the figures examined are taken from American, English, or German returns Detailed comparison is, however, barely possible owing to the wide divergences in the methods of classification adopted by different authors This is well illustrated by Dr Sterling in a table comparing the percentages found by Eardley Holland in this country and those of the U S Bureau of the Census , the former based on the results of autopsy, the latter on clinical examination only

Causes of Fœtal Death or Still-birth

Cause	U S A (Bureau of Census) Per cent	England (Eardley Holland) Per cent
Complications of labour	23 1	51
Diseases or conditions of placenta and membranes	8 9	6
Prematurity (abortion, miscarriage, and premature birth)	8 2	—
Toxiemias of pregnancy	5 2	10
Malformation (congenital defects)	4 1	5
Syphilis	2 6	16
Traumatism and overwork	3 7	—
Other diseases and conditions of mother	3 1	2
Various causes	10 9	—
Not specified and unknown	30 2	10

In examining the causes assigned to neonatal deaths premature birth occupies a prominent position if clinical data alone are available Post-mortem study, however, displaces this group from its prominent position and shows that many of these deaths were, in fact due to complications of labour As Dr Sterling justly remarks " Prematurity, ranking first in the census figures, goes down to fourth or fifth place in the autopsy group A post-mortem examination brings to light the real cause of death in many premature infants, showing that the child did not die simply because it was premature, but that its premature birth and death were both dependent upon some other factor " The other chief causes of both fœtal and neonatal death are of varying magnitude in the different investigations, and are difficult to compare owing to the divergences of classification In most of the American data, compiled on clinical examination only, syphilis is given a very low place, the highest being below 3 per cent The autopsy figures for America show a considerable increase on this figure

Dr Sterling has collected interesting data on the possible relationship of social conditions to fœtal and neonatal deaths The figures collected by the Children's Bureau from eight American cities suggest that the employment of the mother outside the home is unfavourable to survival in the early months of life The infant mortality-rates for different races living in America lead the author to conclude that " early infant mortality varies with racial stock for reasons unknown " On the whole the most favourable rates are those for Italians and Russians The report offers many other points of interest The free reproduction of tables from various authors and the very complete bibliography render it a valuable basis for further investigation Much of the work done hitherto remains isolated owing to lack of uniformity in the basis of classification Until some degree of comparability is achieved any comparison of the causes of fœtal and neonatal deaths in the various countries of the world must be inconclusive

STATISTICAL EPIDEMIOLOGY IN LONDON.

As we announced recently,[1] the London School of Hygiene and Tropical Medicine will begin advanced teaching in bacteriology and immunology this autumn, when Prof W W C Topley will take up his appointment We are informed that Dr Major Greenwood, who, like Dr Topley, was originally appointed a professor in the new school from August, 1928, will also enter upon some of his duties in October of this year and will receive small groups of post-graduate students for three months' or six months' course, in general and statistical epidemiology (Full particulars may be obtained from the Director of the School at 37, Torrington-square, W C 1) Prof Greenwood has always been encouraged by the medical department of the Ministry of Health and the Medical Research Council to receive a small number of post-graduates at the National Institute of Medical Research, where, in virtue of a working agreement between the Ministry and the Council, he carries out statistical investigations of interest to both departments In the past year students from Berlin, Riga, and Madrid have worked with him The method of instruction now in use is described by Prof Greenwood in an article published in the current issue of the *Archiv fur Soziale Hygiene und Demographie* (Bd II , Heft 3, 1927) from which we quote the following —

" My students usually begin by trying out the simplest methods of statistical calculation not upon artificial examples (ausgeartete Kunststücke) but on real data In an official department of medical statistics there are usually data of all kinds to hand, so that the school medical officer can be given measurements of elementary school-children, the epidemiologist statistics of infectious diseases, and so on. After a week or two in which the student gains some self-confidence and learns to handle a calculating machine, tables, and the simpler formulæ, he can tackle the data which really interest him What remains of theory must follow the rule *solvitur ambulando* Of course, a serious student would also read a text-book and seek explanations of difficulties Once or twice a week some particular topic is made the subject of a general discussion For those who seek a wider mathematical training Prof Pearson's Institute offers a rich choice of lectures and practical classes Neither the National Institute of Medical Research now, nor the School of Hygiene in the future, will claim to be able to produce by this method professional statisticians A foreigner who wishes to master the general theory of mathematical statistics must betake himself to Prof Pearson's Institute or to Mr Udny Yule, at Cambridge. I and my colleagues are only competent to help those who wish to employ the statistical method as a useful tool in epidemiological and public health investigations In a word, we are not epidemiological statisticians but statistical epidemiologists "

---

[1] THE LANCET, April 30th, p 937.

No doubt this method will be continued by Prof Greenwood when he formally assumes the professorial functions and it appears to be suited to the requirements of most medical post-graduates

DANGERS OF THE BARBITURIC HYPNOTICS

Since 1902, when the barbituric acid group of drugs was first introduced, there has been a steadily increasing stream of hypnotic preparations of this class The number of proprietary remedies now on the market indicates the rapidity of their rise to popularity and the extensive use which is being made of them by practitioners throughout the world Veronal, medinal, dial, and the like have a certain and speedy narcotic action which is eminently satisfactory, and after their use the patient wakes without objectionable sequelæ Yet prolonged use of these drugs has at times produced symptoms almost identical with those of disease of the central nervous system and Sir William Willcox speaking at a meeting of the Section of Therapeutics and Pharmacology of the Royal Society of Medicine on May 10th, was able to recall two cases one of allonal and one of veronal poisoning, which had been sent to him by a neurologist as undoubted cases of organic nervous disease Ocular palsies, nystagmus, paralyses of the facial nerve or of a limb, polyneuritis, ataxia, remarkable hypotonia of the muscular system, scanning speech, faults of memory and marked emotional instability have all been recorded again and again in chronic cases of poisoning The literature on the subject is indeed enormous as Dr Helen Young found when collaborating with Sir William Willcox and Dr F A Pickworth in the preparation of the paper presented at this meeting Most regrettable of all is the predominance of mental symptoms and especially of depression, leading to frequent suicides The first case of directly fatal poisoning occurred in 1905 and the numbers rapidly increased until 1913 when the group was put on Part II of the Poisons Schedule, in 1918 it was transferred to Part I, and this resulted in a distinct drop but in 1925 the numbers rose again to 22, as the public began to find out the possibility of using medical prescriptions Sir William Willcox said that he regards these statistics as incomplete for additional fatalities from these drugs may be hidden in the class of "narcotic poisoning" or in that of "broncho-pneumonia," since the comatose condition so lowers the resistance of the lungs that a true terminal broncho-pneumonia almost always occurs Most practitioners consider these drugs almost harmless and prescribe them freely, but certain investigators have always had their suspicions, and Sir William Willcox has already sounded a note of warning Never before however has he been so uncompromisingly backed by the weight of solid laboratory evidence Dr Pickworth reported the experiments carried out under rigid control conditions in Sir Frederick Mott s laboratories at Birmingham and showed that continued administration of these drugs produces pathological changes in the central nervous system which although they usually disappear when the dose is discontinued, may nevertheless become permanent The chief phenomenon is the deposition of a homogeneous mucinoid substance in the white matter of the central nervous system, This is believed to be a product of neural metabolism, so that it must have an inhibitory effect on the life of the cells Moreover, it is present in considerable quantity, and probably causes pressure and affects the intracranial circulation Conduction along the nerve-fibres is interfered with, and a large part of the narcotic effect is due to the damping down of visceral afferent impulses When administration of the drugs is still further continued the cerebral cells shrink, lose their processes and stain poorly, and the Nissl substance is found to be reduced or even absent It has been shown that these lipoid-soluble drugs render the lipoid envelope of the cell less permeable, so that tissue-respiration is embarrassed throughout the body There is a capillary dilatation, an increase in the flow of blood and a slowing of the pulse The resemblance between the comatose condition induced by them and the condition of normal sleep is only superficial, and Dr Pickworth found that under the influence of these drugs the margin between sleep and fatal coma in cats was a very narrow one The peripheral parts of the nervous system are most easily affected and the centre more slowly There was definite evidence of a cumulative action, and of the existence of addiction Sir William Willcox had no doubt whatever Nor, he maintained, is tolerance ever established He felt strongly that the danger of these drugs was not properly recognised They should be ordered only on a prescription marked "not to be repeated" and covering only six doses The patient should be warned against daily doses, and preferably only one should be given each week He desired to warn practitioners most solemnly against advertisements which urged the value and ignored the dangers of preparations of the barbituric acid group The poisonous constituent was often concealed under a fancy name, and a note in very small print He regarded the continued introduction of new preparations and the glowing advertisements accompanying them, as seriously misleading to the profession and a grave danger to the public

E 107.

The new anæsthetic E 107 or avertin to which we alluded in a recent annotation (The Lancet, April 2nd, p 718) is further described in the *Deutsche Medizinische Wochenschrift* of April 22nd, and we are informed of its chemical nature, hitherto not divulged. The substance is tribromethylalcohol (CBr_3CH_2OH) It decomposes on long exposure to light or in alcoholic solution From experiments with rabbits it appears that avertin is rapidly eliminated by the kidneys, 50 per cent of the amount administered being passed out into the urine in combination with glycuronic acid. The narcotic action of the anæsthetic is very rapid, and when it is injected intravenously, is almost instantaneous With excessive doses the respiratory centre is rapidly paralysed Further clinical evidence is wanted before the drug can be tried with confidence for operations

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN

The annual general meeting of this Society was held at 11, Chandos-street London, W 1 on May 11th, when the report for the year 1926 was presented The Society has scored in its long wrangle with the Inland Revenue Authorities for refund of income-tax as a charity under the Finance Act In 1925 the Commissioners of Inland Revenue dissented from the decision of the Special Commissioners to grant rebate and requested them to state a case for hearing in the High Court. With income-tax at *4s* in the pound the annual tax would amount to some £940, and the directors of the Society were compelled to reduce the Christmas present in December, 1925, and the grants from the Brickwell Fund in January, 1926 In June, 1926, however, when the case came up for hearing before Mr. Justice Rowlatt in the High Court, the Society obtained judgment with costs. The sum of £1774 has since been received from the Inland Revenue being the amount of income-tax withheld during the last two years. In October, 1926 it was therefore possible to pay the full amount that had been deducted from the grants to widows and orphans. The legal expenses incurred amounted to £276, of which £130 was recovered from the Inland Revenue. A legacy, amounting to £3 935, brought up the total of invested capital to £138,550. Since the last report four members have been elected and one has died. The Society now consists of one hon. member, 161 life, and 141 ordinary members, making a total of 303. The income from investments amounted to £3953, £371 was received from subscriptions and donations, and £42 from life subscriptions. The working expenses were £514. During the year three widows died and one came on the funds, the amount distributed in grants during the year being £5420 8s. At the close of the year there were 49 widows and seven orphans in receipt of grants. Membership in the Society is open to any registered medical practitioner who at the time of his election is resident within a 20-miles radius of Charing Cross. Should a member remove anywhere outside the radius, even beyond the British Isles, he nevertheless remains a member of the Society, provided he has conformed to the by-laws. Relief is granted to the necessitous widows and orphans of deceased members of three years' standing and of life members. The annual subscription for a member who at the time of his election is under 40 years of age is 2 guineas, if over 40 but under 50, 3 guineas, and if over 50, 4 guineas.

IN an article published in our issue of April 30th by Sir Arnold Lawson and Mr. A. L. Whitehead, dealing with the protection of the eyes necessary for those viewing the total eclipse, a description was given of a screen through which observations of the phenomenon throughout all its phases could be made with perfect comfort and safety. We learn, however, that the price of the screen was wrongly stated. Messrs. Hamblin, the well-known firm of opticians of 15 Wigmore-street, London, who have placed the screen "Eclipsia," on the market, state that there are two varieties of the mask which will cost 1*s.* 6*d.* and 3*s.* 6*d.* respectively, whereas the original article in our columns gave the price as 1*s.* We are informed that the cheaper screen is just as effective a filter as the more expensive one, but whereas the former consists of a screen of only one density, the latter, a more elaborate affair, having three grades of density, allows the eclipse to be viewed to the best advantage at different stages.

AN address will be delivered by Sir John Rose Bradford to-day, Friday, May 13th, at 8.30 P.M., at University College, London, the subject being the Relations of the College to Medical Education. The address is the last of four delivered in connexion with the centenary celebrations of the College, the previous lectures having been delivered by the late Prof. Starling on Feb. 28th, Sir Oliver Lodge on March 14th, and Dr. W. R. Chambers on May 2nd. The chair will be taken by Sir George Thane and academic dress and decorations will be worn.

SIR Alexander Houston's twenty-first annual report to the Metropolitan Water Board, which has just been issued (Messrs. P. S. King and Son. 21*s.*) gives the results of the chemical and bacteriological examination of the London waters for the calendar year 1926, and includes an illustrated account of the water-supply from the Kentish Wells.

THE next session of the General Medical Council will commence at 2 P.M. on Tuesday, May 24th, when the President, Sir Donald MacAlister, will take the chair and give an address.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCXXIII

THE TREATMENT OF LUPUS VULGARIS

THE successful treatment of lupus vulgaris, which entails the destruction of the disease with the minimum of scarring, is fraught with difficulty. The clinical types and phases of the disease are so varied that no single method of treatment is suitable for all cases, and, to obtain the best results, not only a knowledge of the different forms of treatment is necessary, but the right selection of the method best adapted to the peculiarities of the individual case. As it is a local disease of the skin, due to the presence of tubercle bacilli *in situ*, the treatment is essentially local. At the same time, the value of the local treatment can be greatly enhanced by combining it with a suitable tonic regime on general medical principles, with plenty of fresh air, good food, outdoor exercise and sunshine, or, where the last is unobtainable, with artificial sunlight from an arc lamp. There is no internal specific for lupus. Thyroid extract, which once had a reputation in this connexion, has almost been forgotten; tuberculin injections have not fulfilled their early promise, and since they are liable to light up latent foci of tuberculosis elsewhere, they are now comparatively rarely employed, except in extensive ulcerated cases, where injections of Koch's tuberculin (T.R.) or tuberculin (B.E.) may be of service in healing the ulceration.

The main objects of local treatment are: (1) the complete removal of the diseased tissue, and (2) the production of as little scarring and disfigurement as possible. The methods employed may be conveniently considered under the headings of surgical, physical, chemical, and radiotherapeutic.

Surgical Methods

Excision.—Where practicable, when the lesions are not too extensive, and are situated on covered parts of the body, excision is the most satisfactory treatment, and even on the face, in the hands of a skilled operator, excellent results may be obtained by it. The incision should be made at least a quarter of an inch beyond the diseased area, and not only the skin, but the superficial half of the subcutaneous fat should be removed. After the excision the surface should be grafted. Krause's deep grafting should be employed rather than Thiersch grafting, since, with the latter, the wound does not heal rapidly, and the scar is liable to be uneven, occasionally keloidal, and may be followed by contraction. Deep grafting consists of transplanting a piece of skin of the exact shape and size of the tissue excised, taken from some suitable part, such as the thigh. The graft should be cut as deep as the fat layer, the fat being scraped off before it is put in position, and it should be slightly larger than the required size to allow for shrinkage. After being placed in position, it is neatly sutured to the edges of the wound. Where the lupus occurs about the mouth, eyelids, and nose, it may be difficult to get the graft to hold, and in such cases some form of plastic operation may be resorted to, employing grafts from a neighbouring part with pedicles, which can be severed when the graft has healed in place.

Scraping is a simpler method than excision, but the results from it are more uncertain. It is apt to leave unsightly scars, and if not sufficiently drastic may lead to a dissemination of the disease by opening up the lymphatics. It should be done under a general anæsthetic by a Volkmann spoon, methodically, thoroughly and firmly, and should reach down to the subcutaneous tissue. Owing to the hæmorrhage associated with scraping it is difficult to distinguish healthy from diseased tissue except by the feeling of resistance to the spoon, the lupus being so much softer than the healthy tissue The hæmorrhage is, as a rule, too profuse to be controlled by pressure, but can be stopped by ironing the surface with a Paquelin cautery In spite of the most careful scraping, small diseased foci are apt to be left To obviate this, the raw surface should be dabbed over with pure carbolic, or smeared with zinc chloride paste, made fresh by pounding up a small quantity of zinc chloride in a mortar with glycerine and water. The surface should then be covered with an aseptic powder, and a dry dressing applied When the wound has healed, it should be carefully examined for foci of the disease which may remain This is best done by a diascope, or piece of glass pressed down on the lesion, when the diseased foci can be detected as semi-translucent brownish specks These may be dealt with by cauterisation with a fine pointed Paquelin cautery, or by acid nitrate of mercury drilled in by a glass pen

Scarification is a somewhat neglected method, which is useful for the destruction of small lesions about the face, as it causes comparatively little scarring It consists of chopping up the nodule by a number of criss-cross incisions, either by a sharp tenotome, or by a special instrument devised for the purpose with several parallel blades The bleeding is controlled by pressure, followed by the application of powdered permanganate of potash, or zinc chloride paste It may be necessary to repeat the scarification should any disease persist after healing

Physical Methods

Cauterisation —Reference has already been made to the use of the actual cautery for the destruction of persistent foci of disease after scraping, and for the control of hæmorrhage For this purpose, the Paquelin cautery, with a point of suitable size, at a dull red heat, is superior to the electro-cautery, as it is more easily controlled and manipulated The disadvantages of the use of the actual cautery, however, are that it is liable to destroy healthy as well as diseased tissue, and to be followed by a hypertrophic scar As the burning is almost instantaneous, small lesions can be destroyed by this means without the necessity of a general anæsthetic

Freezing with solid carbon dioxide is a useful treatment, especially in lupus of the verrucose type For warty patches situated on the extremities, freezings, repeated at intervals of about a week to allow healing to take place in the interval, give better results than any other form of treatment The exposures should be from 30–60 seconds, with firm pressure, the applicator being of suitable size After the freezing, the exposed area should be covered with a simple aseptic dressing until healing has taken place

Chemical Methods

The most important caustics are pyrogallic acid, salicylic acid, permanganate of potash, silver nitrate, zinc chloride, and acid nitrate of mercury Both pyrogallic acid and salicylic acid were once largely used in the form of plasters, generally combined with creosote, or as paste spread on lint These were applied continuously to the lupus patch, until sloughing of the diseased tissue took place This treatment during recent years has fallen largely into disuse, owing to its tediousness and the pain associated with it The same criticism may be made with regard to permanganate of potash which was employed as a powder spread over the patch, and then covered with cotton-wool, or as a 10 per cent solution painted on daily Silver nitrate is still used in the form of a pencil, which is drilled down into the nodule, and is of some service in lupus of the mucous membranes Acid nitrate of mercury is the most useful of the caustics, and is of special value in destroying isolated nodules It consists of one part of mercury dissolved in two parts of nitric acid (specific gravity 1 5) It is applied either on a piece of cotton-wool twisted on a match or by a glass pen, and should be kept in contact with the nodule for at least a minute The application causes the diseased tissue to become white and opaque, and results in the formation of a brownish crust, which becomes detached when healing takes place Where the caustic is applied to small areas comparatively little discomfort is caused by it, but if the patches be of the size of a sixpence or larger, there may be severe pain for some hours after the application

Radiotherapeutic Methods

Phototherapy —Apart from excision phototherapy is generally recognised as the most permanent treatment of lupus, and the one that produces the least disfigurement, the resultant scar being sometimes so slight as to be almost unnoticeable This method is so tedious, however, that its use has to be restricted to lupus of the face and neck, or of the thin skin over joints, where it is important to avoid contracture Long experience of its use has shown that a cure can be effected in 60 to 70 per cent of cases, provided the patient has the time and patience to have the treatment properly carried out Where failure has taken place, it has generally been because the lupus is too deeply situated for the irradiation to be effective, or because the diseased tissue was covered with a cicatrix impermeable to the rays The selection of the best type of lamp is a matter of opinion; the technique should be learned in one of the hospital departments where it is in use

X rays have been extensively used in the treatment of lupus in the past, but their indiscriminate employment for this purpose has done more harm than good In my experience it is impossible to destroy the lupus tissue by this means without causing an X ray burn, possibly followed by epithelioma It has recently been shows that cancer developing in old cases of lupus vulgaris has been much more common since the introduction of the X rays than it was previously. On this account they should be used with the greatest caution I have found that they are of service for the healing of superficial ulcers in lupus as a preliminary to phototherapy, and for lesions in certain situations, such as the eyelids or the mucous membranes, which cannot be dealt with satisfactorily by actinic rays owing to the difficulties of exerting the requisite pressure

Radium is rarely used in this connexion Its action is similar to the X rays, and the results from it are not so satisfactory as those from phototherapy

Conclusion

Unless the disease has been completely removed by excision, recurrences are so liable to take place that the patient must be kept under observation and examined periodically, any foci of disease being immediately dealt with As a general rule, where the lesions are of limited extent, and situated on covered parts of the body, excision followed by deep grafting is the best treatment Where they are too extensive for excision they should be scraped and cauterised For lupus on the face phototherapy gives the best results and where the disease has attacked the mucous membrane, scraping followed by the application of lactic acid, or silver nitrate, or the actual cautery are the most useful methods

SHELLEY MEMORIAL PRIZES —In 1892 the centenary of Shelley was commemorated by the placing of a memorial in Horsham Church and in other ways A balance remained of money subscribed, and this has since been invested so that on Feb 25th the trustees were able to hand over £500 War stock to the West Sussex County Council for the establishment of Shelley Memorial Prizes for Natural Science in the Public Secondary Schools maintained or aided by the Council

Special Articles.

THE CENSUS OF HOUSING IN ENGLAND.

THE General Report of the Census of England and Wales, 1921,[1] now issued, contains much information of interest to medical and other social workers, and the wise worker will study carefully this record of the massed material on which he has to work No part of this information possesses such vital importance as that relating to the housing of the people , and in this article it is proposed to concentrate on this part of the report, showing graphically and otherwise some of the socially most significant facts bearing on this problem

For the census purposes the groups of persons included in a separate census schedule consist of either " private " or " non-private " families The last-named includes people in hotels, hospitals, &c , while a private family may include a lodger boarding with the family, but not a lodger occupying separately part of the house

Thus defined the average number of families per 100 occupied dwellings was 109 in 1911 and 112 in 1921, but owing to the smaller average size of families the number of persons per 100 occupied dwellings was only 485 in 1921 as compared with 493 in 1911

Neither of these figures can be regarded as indicating improvement or worsening of housing without further detailed analysis which is given in the census report

Size of Dwellings

Of the total dwellings 16 9 per cent comprised three rooms or less and 48 8 per cent , or nearly half, contained four or five rooms only Of the total 8,750,000 private families in England and Wales 80 2 per cent were living in the single occupation of separate dwellings, 13 7 per cent were living two families to a dwelling, and in 6 1 per cent of the dwellings there were three or more families

In mitigation of the apparent large departure from the ideal of one family to one dwelling, it should be noted that a single lodger boarding separately from the occupier is regarded as a separate family

Local Distribution of Size of Dwellings —As the chief social interest centres in the smallest dwellings we propose to consider these particularly (Table I)

TABLE I —*Showing for Certain Counties the Proportion per 1000 Total Dwellings having One to Three Rooms*

Highest		*Lowest*	
Northumberland	538	Isle of Wight	50
Durham	458	Middlesex	60
Yorkshire, West Riding	340	Surrey	61
Cumberland	252	Sussex, West	75
Yorkshire, North Riding	213	Sussex, East	87
Worcestershire	206	Devonshire	134
Warwickshire	199		
Yorkshire East Riding	195		
London	181		

Northumberland and Durham stand out in respect of their very high proportions of dwellings of the smallest type Not only so, but on the average these small dwellings are occupied by a larger number of families than obtains elsewhere But the data so far illustrated do not give us an adequate idea of housing conditions, and it is necessary to consider also

Size of Family in Relation to Number of Rooms Occupied

This distribution for England and Wales as a whole is shown graphically in Fig 1 It will be seen that in 1921 only 46 0 per cent of the private families occupied dwellings containing five or more rooms as compared with 49 6 per cent in 1911 This is a slight indication of the general tendency in recent years to occupy smaller houses or flats The proportion of four-roomed dwellings is almost the same at the two censuses , but it will be seen that the proportion living in smaller dwellings of one, two, or three rooms has increased in recent years

The average size of family has dropped by 5 per cent from 4 36 persons in 1911 to 4 14 in 1921, a natural result of the increase in the marriage-rate, along with the greatly reduced birth-rate and the heavy mortality in the war

To ascertain whether the population in 1921 was really rather less densely housed than in 1911, further details are needed, especially in view of the general declaration of house shortage throughout the country

We may first take the statement of *average number of occupants per room* in the entire country The relative proportions are shown in the following table, omitting persons living in tenements of over nine rooms It should be noted that in the enumeration of rooms kitchens are included, but not sculleries, bathrooms, or offices or shop rooms Thus stated the average results do not differ greatly at the two censuses (Table II)

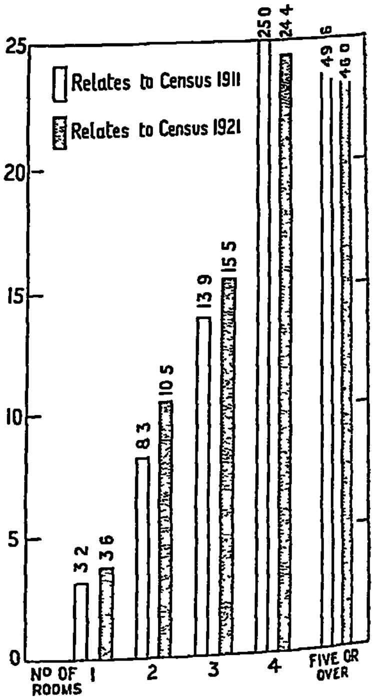
TABLE II —*Proportion per cent of the Total Population Living with (on an Average)*—

Per Room	*1911.*	*1921*
Less than one person	31 7	32 5
One person	15 0	16 1
One to two persons	39 1	38 4
Two to three persons	7 6	7 8
Three persons and over per room	1 5	1 8

It will be seen that for 9 6 per cent of the population there are more than two persons to a room The ratio of more than two persons to a room has been taken in 1921, as in the preceding census, as an approximate index of the prevalence and distribution of overcrowding

The utility of this ratio is undoubted, although it has been criticised It does not, of course, distinguish between large and small rooms, but it is probably the best measurement we have, at present, of relatively good or deficient housing accommodation The percentage 9 6 compares with 9 1 in 1911 More detailed figures than are given above show that, excepting families comprising only one person, for whom there is obviously no scope for improvement, " a deterioration has taken place for all sizes of family, including the larger families whose density was already approaching the region of overcrowding " The amount of worsening during the ten years is approximately 3 per cent

FIG. 1.



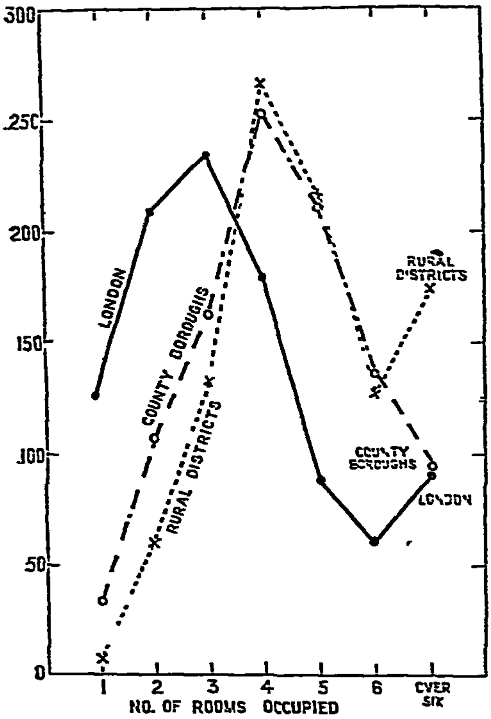
Comparison of Urban and Rural Districts

The distribution of families (per 1000 total families) according to the number of rooms occupied in 1921 is shown in Fig. 2 for London county boroughs, and rural districts in the aggregate respectively. It will be seen that the smaller units preponderate in London to a much larger extent than in the average of county boroughs and of rural districts This is doubtless in part due to the much larger proportion of lodgers in London to total population. In London the most frequent unit of occupation is three rooms; in boroughs and rural districts it is four rooms In London 13 2 per cent of the total families live in single rooms as compared with 3 4 per cent in the county boroughs and 0 7 per cent in the rural districts The approximation of the urban to the rural death-rate and particularly the approximation of the death-rate from tuberculosis in urban and rural areas, is noteworthy in view of these figures

---

[1] H.M Stationery Office 1927 5s

FIG. 2.



The marked and consistent superiority of housing in the rural areas is further shown in Table III in which is given the proportion per 1000 total population living in private families with the average numbers of *rooms per person*, for dwellings with the greatest room-density

TABLE III

—	Census 1911 Less than half a room per person	Census 1911 Half to one room per person	Census 1921 Less than half room per person	Census 1921 Half to one room per person
London ..	178	409	161	413
Aggregate of—				
County boroughs	94	415	108	404
Other urban districts	74	383	81	380
Rural districts	66	360	65	350

Both in 1911 and 1921 the superiority of rural over urban housing of the housing in the smaller urban districts over those in the county boroughs and of that in the average for the county boroughs over London housing is most striking

But far and away the most important tables in this census report—tables which should be thoroughly studied by every medical officer of health and sanitary inspector—are Tables XXVI. and XXVII., which give for each administrative county, for each metropolitan borough, and for each of the larger towns its average condition as tested by various tests of adequacy of housing

Degree of Local Overcrowding

These tests are (*a*) the average number of families per dwelling; (*b*) the room-density or average number of rooms per person. (*c*) the last test in which variations associated solely with differences in size of families have been eliminated; and (*d*) the proportion of persons living in overcrowded conditions which is taken as represented by densities of less than one-half a room per person For our present purpose we take the last-named test It is evident that it is more likely to give valuable indications of circumstances affecting health than the three other above-mentioned tests For the country as a whole 9 6 per cent. of the total population is within the defined overcrowding limits In Northumberland and Durham which here also are the worst in the series, the proportion is 30 8 per cent and 29 5 per cent respectively; in London it is 16 1 per cent. in the West Riding 11 5 per cent in Stafford 11 1 per cent, in Cumberland 10 6 per cent in Denbigh 10 1 per cent, and in the North Riding of Yorkshire 9 7 per cent

Overcrowding in Metropolitan Boroughs—In London the following extremes of overcrowding—as defined above—are seen (Tables IV A and B)

TABLE IV A.—*Proportion per cent of Population Living more than Two per Room*

Worst	1911	1921	Best	1911	1921
Finsbury .	39 8	34 0	Lewisham	3 9 .	4·7
Shoreditch	36 6	32 0	Wandsworth	6 3 ..	6 8
Stepney	34 9	29 0	Hampstead .	7 1	6 5
Bethnal Green	33·2	27 8	Westminster	6·3	7 8
Southwark .	25 8	23 5	Woolwich	12 9 .	10 1
St Pancras	25 5	22 4	Hackney	12 4	11 5
Bermondsey	23 4	23 2	Greenwich	12 1	13 8

TABLE IV B—*Overcrowding in Large Towns*

Worst	1911	1921	Best	1911	1921.
Gateshead .	33 7	37 0	Northampton	1 1 .	2 7
South Shields	32 9	36 5	Oxford .	2 4	2 3
Newcastle-on-Tyne	31 6	33 6	Great Yarmouth	2 5	2 1
Tynemouth	30 7	34 4	Ilford . .	2 1	3 1
Sunderland	32 6	33 8	Luton .	3 1	3 7
St. Helens	17 0 .	21 0	Gillingham .	2 3 .	3 4
Wigan .. .	12 9	15 3	Derby .	1 9 .	3 5

The tables from which the above extracts have been made throw much light on the relative degree of room-density in different districts Their teaching is so obvious as to require little or no comment The comparisons between 1911 and 1921 are also interesting. In London the small reductions in room-density shown in most metropolitan boroughs are not so great as might have been anticipated in view of the reduced birth-rate. The worsening shown in the coal-mining and iron centres in the north is not surprising, as in these districts the reduction in the birth-rate has been relatively small There is abundant evidence in these important tables of the need for further housing provision especially for those who need two, three, or four rooms only.

Institutions in Relief of Housing

It is too little recognised that hospitals Poor-law institutions asylums, homes for cripples blind &c, house a considerable proportion of the total population at any given time and that were it not for this steadily increasing provision modern difficulties in housing would be immensely greater than they now are The relief thus given is the more significantly important. inasmuch as it is given on behalf of those who otherwise would suffer most by remaining in their exiguous homes and who if they remained there might injure the health or reduce the efficiency of those remaining at home The figures published in the census report give a clue to the amount of relief to housing thus achieved

The institutions whose numbers are tabulated comprise workhouses and other Poor-law institutions, homes for lunatics, &c , homes for cripples, blind, deaf and dumb, hospitals and convalescent homes, prisons and reformatory schools, and some others Only some of these are enumerated in Table V

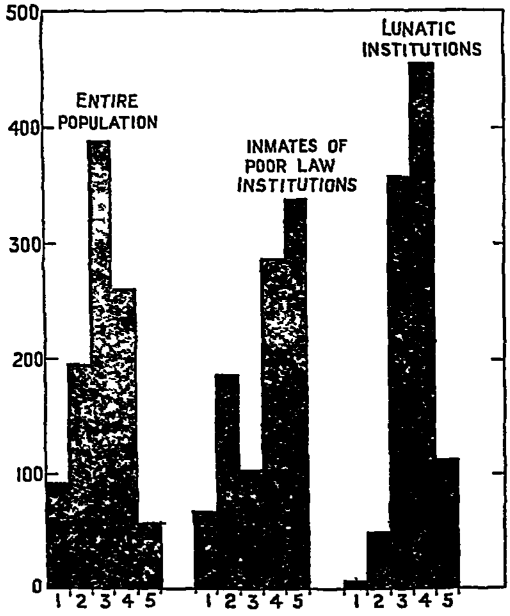
TABLE V —*Proportion per 10,000 of the Total Population of England and Wales who at the Census were Resident in Institutions (Inmates only)*

Workhouses and other Poor law institutions	49
Lunatics, &c	32
Hospitals and convalescent homes	28
Homes for cripples, blind, deaf and dumb	2 2
Reformatory schools	4 2

In addition prisoners comprised 3 per 10,000 of the population

The age-distribution of inmates of these institutions has much social interest, and we may in conclusion give this distribution for the most important of these (Fig 3)

FIG 3 —*Age-distribution per 1000 Males at all Ages in Poor-law Institutions and Asylums*



1 At ages under 5 2 5–15 3 15–40 4 40–65 5 Over 65

In the first set of columns is shown the age-distribution of the male population of England and Wales at five periods of life , in the second the same is shown for Poor-law institutions, and in the third for homes for lunatics It is clearly seen that the majority of patients in asylums is at ages 15–65, while the majority of occupants of Poor-law institutions are over 40 and especially over 65 years of age Old age pensions have reduced the proportion in institutions at these higher ages, but it still remains true that Poor-law institutions serve chiefly for the care of persons disabled by age combined with infirmity

---

DUBLIN VICTORIA EYE AND EAR HOSPITAL —A new wing is being added to this institution and it will be opened a few months hence It is the only hospital in Dublin devoted exclusively to the treatment of diseases of the eye and ear, and the annual report shows that last year there were 1820 in-patients and 9905 new out-patients in addition to 2836 out-patients receiving further treatment

---

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

ANNUAL CONGRESS

(*Concluded from p 992*)

THE Thursday evening session was opened by a paper, read by Dr GORDON HOLMES, on

Tumours involving the Chiasma, excluding Pituitary Tumours

He said that when meeting with cases of intracranial tumour suggestive of a lesion of the chiasma it was usual to think of a new growth of the pituitary body He had noted that in a considerable proportion of these cases the tumour did not take origin in the pituitary itself , indeed in his experience 40 per cent of tumours causing these symptoms did not do so The other tumours which might compress the chiasma or otherwise interfere with its functions included tumours growing from the pedicle of the pituitary and of these there were two types (1) simple cysts of Radcliffe's pouch, (2) adamantinoma, a variety of epithelial tumour characterised by a peculiar arrangement of epithelial cells Or there might be tumours growing from the base of the brain, teratomata being common in this situation, or primary tumours of the choroid plexus, and of the third ventricle involving the chiasma Another type of tumour was that which arose from the meninges, the commonest being the endotheliomata Tumours might spring from the basisphenoid and involve the chiasma, or the basisphenoid might be the seat of malignant growths, such as primary sarcomata or metastatic carcinomata Or tumours—e g , aneurysms—might grow from vessels Dr Holmes quoted a number of cases in each group

Dr A W MULOCH HOUWER read a paper on

Keratitis Filamentosa and Chronic Arthritis,

in which he drew attention to the association between a form of conjunctivitis (later becoming keratitis) and arthritic disability of a chronic and lasting character, which proved very resistant to treatment

Mr J. GRAY CLEGG discussed the paper, and said he had generally used for the condition a mild application of borax and salt, with drops of paroleine When there were definite adhesions of the cornea he used ammonium chloride One of his patients had peliosis rheumatica, and there was an absence of tear secretion

Colonel H HERBERT read a paper on

Glass Membrane Formation in Iridocyclitis

It dealt with the question of the formation of a glass membrane in the anterior chamber, which he considered took place by means of cells which had migrated from the ciliary epithelium It could only be found in very chronic cases of iridocyclitis The paper was illustrated by a large number of microscopical slides

Mr TREACHER COLLINS discussed the paper and Colonel Herbert replied

Mr G F ALEXANDER sent two papers which were read, one on a new method of controlling the eye in the operation for cataract, the other on a factor in the causation of keratitis striata

Edward Nettleship Prize

The PRESIDENT presented this prize to Mr C Howard Usher in recognition of his original work which was, he said, of value not only to ophthalmology but also in a wider sphere If in the future eugenics should become a science it would be largely through such spade-work as that which had been done by Mr Usher

Ætiology and Treatment of Hypopyon Ulcer

The discussion of this subject occupied the whole of Friday morning

Mr J **Gray Clegg** said that in 27 years on the staff of the Manchester Royal Eye Hospital he had had 160,000 patients under his care, 9576 of whom had been in-patients Of the in-patients, 4 per cent were cases of hypopyon ulcer, and of the whole number 0 24 per cent Of the 399 cases, 77 per cent were males, 23 per cent were between 51 and 60 years of age, 19 per cent were over 61, 18 per cent were between 41 and 50, whilst 12 per cent were under 10 Between the ages of 21 and 30 the percentage was 8 In 53 per cent there was a definite history of trauma Miners and labourers were by far the chief sufferers, the miners accounting for 20 per cent of the cases and the labourers for 15 per cent The condition was not found in pit ponies, and was not caused by infection from underground stables, as the draughts of air were always forced towards those stables In the opinion of Maitland Ramsay, ulcus serpens formed 3 per cent to 4 per cent of all underground non-fatal accident cases Most of the subjects of this condition seen by Mr Clegg were below par in general health, and addiction to alcohol had a distinct influence in lowering resistance to infection, while it also hindered recovery The large number of cases in children he thought was accounted for by septic infection in debilitated subjects Such ulcers might be associated with infectious disease, but these cases seldom came to an eye hospital Conjunctivitis was present in 26 per cent of his cases, dacryocystitis in 13 per cent (MacNab gave the proportion of dacryocystitis as 40 per cent) All ulcers with hypopyon were due to the action of micro-organisms, and mostly the culprit was the capsulated pneumococcus of Fränkel and Weichselbaum, though others could cause the condition

Treatment —General treatment, said Mr Clegg, was very important Diet should be simple and nourishing, mild purgatives being given, and morphia or codeia might be needed to relieve pain Any defective teeth must be put right or extracted With regard to local treatment, if there was a definite purulent discharge a bandage retarded recovery by retaining the secretions and thereby bathing the ulcer region in toxic fluid Among the lotions which had been used were 1 in 10,000 hydrarg perchlor, zinc suplh gr 1 ad ℥ i, mercurophen 1 in 8000, formalin 1 in 2000 or weaker Among the drops used were argyrol, 10 per cent to 50 per cent, protargol 5 per cent to 10 per cent, dionin in strengths up to 10 per cent, adrenalin 1 in 1000 Of powders, iodoform, xeroform, nosophen, and airol had been employed Hydrarg perchlor had been used up to even 1 in 100 for direct application to the ulcerated surface only The consequent burning sensation, it was found, could be alleviated by instilling drops of holocain Another preparation having the same effect was trichloracetic acid in a 10 per cent or 20 per cent solution Others were solutions of nitrate of silver, absolute alcohol, pneumococcal serum, and hydrogen peroxide The application of dry heat to the lids by means of the Maddox electric pad, or moist heat by hot pads of lint repeatedly wrung out in hot water to which had been added a little starch, was beneficial Or heat could be directly applied to the ulcer by a cautery knob or loop at a dull red heat being held near the ulcer, thus drying its surface repeatedly For caustic effects, carbolic acid liquefactum was a favourite agent, as it did not penetrate the tissues too deeply A very accurate method was by means of a Paquelin's benzol vapour cautery Dacryocystitis when present must be dealt with When it was mild, in might suffice to wash out the lacrymal passages twice or thrice daily, or argyrol might be introduced into those passages But when there was much discharge or pressure on the sac, the best way of preventing reinfection of the ulcer was by total excision of it or by complete destruction of the mucous membrane When the tension was raised paracentesis was indicated Frequently the necrotic mass was scraped from the surface of the ulcer especially at its advancing edge A more heroic method was to make the Guthrie-Saemisch section, which lowered the tension and ensured a long-continued drainage of the anterior chamber, making it easy to deal with the hypopyon With regard to treating complications, iritis called for the vigorous use of atropine in the form of watery or oily drops If a case was going on well the hypopyon or pus needed no special treatment, but if it was large and fibrinous it must be evacuated In many cases the tension was raised, and then the aqueous should be allowed to escape very slowly, prolapse of the iris might occur if it escaped quickly

Prophylaxis —It could not be too much impressed upon workers that a watery or discharging eye was a serious affair, and that an ophthalmic surgeon should be seen at the first sign of trouble after an injury, however slight Risk of damage to the eye was largely reduced by wearing goggles

Mr S H **Browning** dealt with the subject from the bacteriological standpoint He said he had always found the pus of hypopyon to be sterile, and it had remained so until the time of perforation It was possible to imagine an infection so acute as to paralyse the defensive mechanisms of the eye, so that no hypopyon arose, and it might be such a low infection, and the response might also be so low, that hypopyon resulted Arguing thus, it seemed that hypopyon could be regarded as a sign of good response to the toxic stimulus He had asked ophthalmic surgeons of his acquaintance whether they considered the presence of a hypopyon in an ulcerated cornea as of serious prognostic significance Of 17 who were asked, 11 said they considered it made the condition a more dangerous one, four said it did not matter, two were doubtful The organism most frequently associated with hypopyon ulcer was the pneumococcus, and in order that it could become established on the corneal surface, that surface must have sustained some damage Probably the body causing the injury did not infect; infection was caused by the entry of the organisms already in the conjunctival sac It was of interest that it was rare for ulcers to occur in cases of acute pneumococcal conjunctivitis, or in its less acute form seen in babies Cultures should be taken from the advancing edge of the ulcer He suggested that a bacteriological examination should be made of all ulcers, this step might save many corneæ from drastic treatment later He had never seen the diplobacillus concerned in an intraocular infection The most virulent cases of hypopyon ulcer he had ever seen were due to the *Bacillus pyocyaneus*, and he believed it to be the worst organism which could affect the eye In some of the cases of pyocyaneus infection of the eyes he was able to trace the source to discharge from the ear Streptococci did not now seem to affect the eyes so often as formerly, and hypopyon ulcer due to staphylococci was, in his experience, rare, though he had seen a *panophthalmitis* due to *Staphylococcus citreus* Ulcers caused by the pneumobacillus were not uncommon He had not had any great success in treatment of hypopyon ulcers by bacteriological methods except in gonococcal infections in the adult He was not convinced that autogenous vaccines produced improvement In conclusion, he referred to the magnesium sulphate and hexamine treatment of hypopyon ulcers, the latter drug being given internally in doses of gr 10 thrice daily If irritation of the bladder developed the dose of hexamine was reduced

Mr M S **Mayou** showed a slide depicting a very early stage of pneumococcal corneal ulcer, which followed the entry of a foreign body The ulcer was cauterised with pure carbolic and did not spread The smear preparation was filled with pneumococci He described, by means of a series of slides, the development of these ulcers

Mr W H **McMullen** said these ulcers were now less common than 25 years ago In most cases this disease was preventable, therefore prophylaxis should have the first consideration It was especially important to protect the eyes from accidents in industry, and also that treatment for even slight injuries to them should be skilful He now employed the galvano-cautery in all hypopyon ulcers, except in cases of slight ulceration with little hypopyon The lotion he used was a half-saturated solution of magnesium sulphate, used as an eye-bath for five minutes every two or three hours He preferred not to bandage these eyes, as the warmth and immobility favoured bacterial growth The discussion was continued by Mr A C HUDSON, Dr FREELAND FERGUS, Mr EDGAR STEVENSON, Mr H MACNAB, Colonel A F MCCALLAN, Mr M HEPBURN, Colonel H HERBERT, Mr CHRISTIE REID, Major R E WRIGHT, Mr A L WHITEHEAD, Sir ARNOLD LAWSON, Mr J ROWAN, and Dr HUGH JONES

In the afternoon a large number of clinical cases were demonstrated at the Eye and Ear Hospital, and on Saturday morning the following papers were read and discussed —

Mr M S. MAYOU Distension of the Neural Canal in the Embryo in relation to Microphthalmos

Miss IDA C MANN The Nature and Boundaries of the Embryonic and Adult Vitreous Humour

Mr FRANK JULER A case of Lid Sarcoma with Secondary Growth, apparently cured by Radium

Mr T C SUMMERS A case of Papillœdema in a Pedigree Bull

Members dined together at the Adelphi Hotel, and Mr BERNARD CHAVASSE organised an ophthalmic museum, which remained open during the Congress sittings

MEDICINE AND THE LAW.

Parental Responsibility for Education of Defective Child

MANY years ago it was decided by the law courts that, when a husband was away at sea, his wife might be liable for neglecting the parental duty of sending her daughter to school Lord Coleridge, Chief Justice, pointed out that any other decision would mean that the children of a seafaring population might be left entirely without education Now there has arisen a further question of parental responsibility when the child is a mental defective and the father is in prison Under Section 53 of the Education Act of 1921 the normal duty of a parent to cause the child to receive sufficient elementary education is converted, when the child is defective or epileptic, into the duty to cause the child to attend a special class or school if there is one within reach of the child's residence, the section goes on to say that a parent is not to be excused from this duty by reason only that a guide or conveyance to the school is necessary The following section enacts that the local education authority, after consultation with the parent of a defective or epileptic child over 7 years of age, if satisfied that the parent is not making suitable provision for the child's education, may require the parent to send the child to a certified class or school of a suitable kind , if the parent fails without reasonable excuse to do so the local authority may apply to the magistrates for an order Last October complaint was made by the Somerset County Council that a woman living at Burnham-on-Sea had failed without reasonable excuse to send her defective daughter to a special school provided at Bishops Lydeard *The child, a girl of 12,* was at all material times residing with and was in the actual custody of the mother an important fact, because the Education Act defines the "parent" of a child as including every person who is liable to maintain or has the actual custody of the child The mother was stone deaf, the father was serving a sentence of penal servitude in Maidstone gaol The mother said she refused her consent because she thought the child would be better off at home in her own charge than at a school where she would be liable to punishment, she said the child could do housework and she believed the child was by reason of defective intelligence incapable of benefiting from instruction in a special school. In this belief she was confirmed by her doctor who gave evidence that the child was feeble-minded, of an emotional temperament, better kept at home in her mother's care, and more likely to benefit by association with normal children than with other defective childen at a special school The medical officer had certified the child to be defective and the magistrates, being satisfied that the certificate was correct, ordered the child to be sent to the special school at Bishops Lydeard A number of ingenious points were then taken on behalf of the mother on appeal It was argued that the parent meant the father if he was alive and his address was known, that the father had never been consulted by the local authority, had not been required to send the girl to the school, and had not refused consent or unreasonably withheld it It was also argued that the mother was acting with the bona fide intention of benefiting the child, that the mother had not unreasonably withheld consent, and that the medical officer's certificate was wrong The main argument was that the father, though undergoing penal servitude at Maidstone, was the "parent" for the purpose of the Act He was in prison, it was said but he had not ceased to be a father The King's Bench Division, however, was not impressed by this contention The local authority had to be satisfied under the Act that the parent was not making suitable provision *for the child's education* The Lord Chief Justice said it would be grotesque if this father were allowed to say that to his regret he was in a place where it was not possible for him to comply with the requirement of the statute The child's education could not be left neglected while the father completed his term of penal servitude Thus common sense prevailed, and the decision of the magistrates was upheld

Meat and Malt Wine

The same court on the same day gave an important decision on the sale of "Extract of Meat and Malt Wine" An inspector under the Sale of Food and Drugs Acts had prosecuted[1] a defendant at Salford *for selling him a bottle of extract* to the prejudice of the purchaser, and not being of the nature, substance, and quality demanded The bottle, which cost *4s 6d* , was labelled "Extract of Meat and Malt Wine—Guaranteed prepared from Liebig's Extract of Meat—This wine will be found invaluable as a stimulant to digestion—A tonic and a food—non-alcoholic" The city analyst of Salford certified that the sample contained 81 2 per cent of water, 16 4 per cent of total sugars, and 2 4 per cent of other extractive matter , in this last item was 0 06 per cent of phosphoric anhydride, indicating the possible presence of not more than 2 per cent of a mixture of equal parts of meat and malt extracts The certificate further stated that no change had taken place in the article which would interfere with the analysis, that a genuine meat and malt wine should contain at least 5 per cent of a mixture of equal parts of meat and malt extracts with a wine basis, and that the sample was not a meat and malt wine

As in similar cases heard in the courts *before,* the magistrate seems to have been misled by the fact that no standard of quality is officially fixed for extract of meat and malt wine Here was a sample certified to be 60 per cent deficient of the minimum *amount of meat and malt extract as well as* being entirely deficient of wine , but, as there was no statutory prescribed minimum, it was possible to argue that the meat and malt ingredient was present however disproportionately small and that its sufficiency or insufficiency was a mere matter of opinion Taking this view the magistrate dismissed the information The King's Bench Division, however, decided that the magistrate was wrong The magistrate erred in supposing that, merely because there was

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH

Swindon

THE following statistics are taken from the annual report for 1926 :—

Population, 57 320 Birth-rate, 17 1 Death-rates per 1000 of the population . all causes, 10 7 , tuberculosis, 0 70 cancer, 1 31 ; respiratory diseases with influenza 1 6; heart disease, 2 0 Death-rates per 1000 births neonatal, 23 , infant 48 , maternal from childbirth 7 1.

Dr Dunstan Brewer reports that 1926 was the healthiest year in the history of the borough in spite of unemployment and the coal shortage. The former has not exercised any tangible influence up to the present and the latter, he considers, was favourable to the public health because it improved the atmosphere Unemployment caused the amount of "free" milk for mothers and infants to be nearly doubled. Among general sanitary conditions there are three that require attention The littering of roads with waste paper, &c , chiefly originating from fish-and-chip shops , the fouling of the footways by dogs, which he thinks has been dealt with satisfactorily in other towns; and spitting Since the 1925 Meat Order came into force the carcass of every animal slaughtered in Swindon has been inspected, and the amount of condemned meat is about double what it was Butchers in towns where the Order is enforced complain of unfair competition from districts where it is ignored

During the year 392 new houses were erected. 21 by the corporation outside the borough , 100 additional municipal houses are under construction, 96 without and 4 within the borough. As the increase of the population was 440, the 392 new houses helped to diminish the housing shortage. There is still, however, a great call for houses of the cheapest and simplest construction, and the only solution appears to be the provision by the community at an unremunerative figure of houses for people with large families and small incomes, amongst whom overcrowding is not being diminished Although Swindon has no slums a fair number of houses ought to be demolished when possible. Many, for example, lack facilities for food storage and have no properly placed sinks, nor w c 's with flushing apparatus Two favourable factors in Swindon are the large proportion of houses owned by the occupiers and the supply of cheap electricity.

The hospital accommodation is inadequate. The Victoria Hospital (36 beds) takes mainly surgical cases The Great Western Railway Hospital (12 beds) has a temporary building in course of construction to contain 30 beds The maternity hospital (13 beds) is to be replaced by a better one. The isolation hospital has 70 beds, the venereal diseases hospital 6 beds, and the small-pox hospital 12. The most urgent need is for medical beds, but provision is also required for special departments—nose, throat, ear, eye, &c.—and for mental patients not suitable for an asylum. At the end of 1926 it was decided to apply the full service available for school-children, including dental, orthopædic, ophthalmic, and throat treatment, to ex-babies The new maternity hospital will include a six-bed ward for disorders of infancy.

At the maternity hospital there were 222 confinements One case notified as puerperal fever and 11 of puerperal pyrexia all ended in recovery. There were 3 maternal deaths and the 15 stillbirths included 5 breech presentations and 3 antepartum hæmorrhages One infant developed pneumococcal pneumonia on the third day, and it is thought that the infection was brought by the father from a house where there was a case Dr. Brewer emphasises the need for better facilities for treatment of puerperal insanity Three women with this condition were removed to the fever hospital, were treated without certification, and left the hospital cured without themselves or anyone else knowing that they had been temporarily insane. Fortunately they were also notified as puerperal sepsis Under ordinary methods of treatment these cases are either left at home or removed to an asylum and in both events their future lives are probably wrecked Antenatal work makes progress There were 261 new cases and 45 old cases on the books, accounting for nearly a third of the total births Dr. Brewer records the deaths of 11 women in connexion with childbirth during the year (the death-rate given above being calculated on the Registrar-General's classification of 7 deaths from this cause), and describes maternal mortality as " the blackest spot in the whole of the practice of medicine " He insists that " the first business of any endeavour is to explore the position to sweep away all subterfuges, and reveal the true facts without any attempt at prevarication ' Such a policy gave good results in dealing with ophthalmia neonatorum. He points out that 7 of the 11 deaths could have been prevented by timely interference Bacterial examination in the eight cases of ophthalmia neonatorum revealed the gonococcus in three cases, the pneumococcus in two cases, and a doubtful bacillus in one case In two cases no organism was found, but Dr. Brewer points out that not infrequently the gonococcus cannot be found in the acute stage, but is found later. He suggests that the occurrence of the pneumococcus as a cause of ophthalmia is a ' point of considerable interest."

As in previous years a careful investigation was made of all the deaths which occurred under the age of 17. The 49 infant deaths when reclassified included 18 due to prematurity, 11 to ill-feeding, and 2 to congenital syphilis. Of the 45 cases of scarlet fever notified since April 1st, 1926, 11 were traced to one carrier and 7 to another One case of human glanders occurred in a person who had nothing to do with horses : the source of infection could not be traced. Notification of tuberculosis during the last three years has been carried out efficiently. The pathological laboratory of the public health department was completed during the year and bacteriological examination of milk is to be undertaken.

SOUTH AFRICA

(FROM OUR OWN CORRESPONDENT.)

Hookworm Infection on the Rand

THE presence of hookworm infection in the gold mines of the Witwatersrand has recently been brought to notice. The disease has been introduced by East Coast natives imported into the Union, and the infection has apparently spread to British South Africa natives and to a few Europeans. In 1911 it was reported that 90 per cent. of Mozambique native workers in the mines and on the cane-fields were infected, but no evidence of soil infection was obtainable and it was presumed that the larvæ were killed in the acid water percolating through the soil. A report has just been published by Prof. W. O. Fischer and Dr. A. J. Orenstein giving the result of investigations they have made on the subject. These investigations are not quite completed, but so far they demonstrate many important points.

No evidence has been found to back up the surmise that the acidity of the water in the mines destroyed the larvæ. Investigation of fæces of patients admitted to the City Deep Native Hospital showed that 19 per cent. of the patients were infected with hookworm. In the majority of cases there were no clinical manifestations which would lead one to suspect infection. Marked anæmia was present only in a small number of cases and in only one was the general condition of the patient such as to point definitely to a clinical diagnosis of hookworm infection. It was further shown that of the East Coast natives 25 per cent. were infected, whereas of the British South Africa natives only 8.8 per cent. were infected. Investigation of the soil of four mines has been carried out and in all cases hookworm larvæ were found either on the floors of latrines, in the vicinity of latrines, or near drinking-water containers. In one case larvæ were found under the tram-rail of a main drive. Practical prophylaxis so far as mine-workers are concerned therefore amounts to protecting the mine soil against pollution, and to mass treatment of infected natives. One of the recognised methods of prophylaxis—i.e., the wearing of boots as a protection against infection—can be little used under the local mining conditions.

At a meeting of the Transvaal Mine Medical Officers' Association this report was discussed and the following recommendations were made:—

1. That all East Coast natives recruited for mines be treated with carbon tetrachloride prior to distribution to the mines, and that a similar treatment be given at the mines a week after recruitment. Voluntary East Coast natives to be included. The treatment of British South Africa natives to be deferred for future consideration. Estimated cost of this treatment is £1500 per annum.

2. That all underground and surface bucket latrines be constructed in conformity with the principles recommended in the report, and existing latrines not conforming thereto be immediately reconstructed.

3. That the sumps of these latrines be daily cleaned and freely swabbed out with a 2 per cent. solution of an efficient coal-tar disinfectant, and that a half-inch layer of the disinfectant be left in the sump. The floors, walls, and perches of the latrines to be swabbed daily with the same disinfectant.

4. That more stringent supervision be exercised to prevent natives defæcating in disused stopes.

5. That fæces from underground be removed only in hermetically sealed buckets.

6. That floors and walls of cages and skips, in which buckets are hauled, be effectively swabbed out with a 2 per cent. solution of coal-tar disinfectant immediately after the completion of the haulage, and before they are used for other hauls.

7. That 2 per cent. coal-tar disinfectant be heavily sprayed daily on the foot-wall in the immediate vicinity of latrines and drinking-water tanks.

8. That all East Coast natives admitted to hospital receive at least one carbon tetrachloride treatment before discharge from hospital.

Pneumonic Plague

On April 7th a man was removed from the R.M.S. *Armadale Castle* as a case of suspected pneumonic plague. The patient died and the diagnosis was confirmed post mortem. The mail-boat was put in quarantine at once and passengers were warned that they sailed at their own risk. Since then wireless reports show that there have been no further cases on board. The exact source of infection has not been traced, but plague is still present in certain areas of the Union—particularly in the Orange Free State and in the north-eastern part of the Cape Province—although the coastal belts are reported free of infection. The Department of Public Health keeps up a continuous campaign against rats and gerbilles, but the rodent question is a very difficult one in a country of this size.

Sir Edmond Stevenson

The death occurred at Rondebosch, Cape, on April 16th of Sir Edmond Sinclair Stevenson, J.P., F.R.C.S. Edin., in his seventy-sixth year. Sir Edmond Stevenson was the son of William Ford Stevenson and was born in 1850 at Geneva. In 187-, after studying medicine at the University of Edinburgh, St. Thomas's Hospital, and then in Paris, Brussels, and Berlin, Sir Edmond Stevenson first came to this country, where he eventually became one of the leading members of the profession. He began by practising at Malmesbury, Cape, and later moved to Rondebosch. Sir Edmond Stevenson was medical adviser to Cecil Rhodes and to Dr. Jameson, as well as being a great personal friend of Rhodes. He served in the Transkei native campaign, the Boer War, and the Great War, and was knighted in 1905. He took a great part in the public and social life of the Peninsula. He leaves a son and two daughters.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Medical Registration

THE Medical Practitioners Bill, of which a summary was given last week, passed its second reading in the Dail on May 4th, and has since been considered in committee. On the motion for the second reading Mr. McGilligan, the Minister in charge, explained the provisions of the Bill, and the motion was carried unanimously and without debate. Further study of the Bill brings to light some points omitted in the abstract given last week. Casual vacancies on the Free State Council are to be filled as they occur by the body in whose representation the vacancy has occurred, but this does not apply to casual vacancies among the direct representatives of the profession, which are to be filled by election by the Council itself. Such a procedure is vicious in two respects. It disfranchises the registered practitioners partially or completely, perhaps for several years, and it may exercise an improper influence on the choice of the practitioners at the next regular election. It is not unlikely that this clause will be amended before the Bill becomes law.

In the agreement between the authorities of Great Britain and those of the Free State, which forms the foundation of the Bill, there is a hiatus which may lead to misunderstanding in the future. It seems to be assumed that the General Council will no longer have disciplinary control over persons registered in the General Register who practise in the Irish Free State. There is no such proviso in the agreement, and it seems as if it would still be the duty of the General Council to investigate the conduct of persons registered in the General Register, wherever they reside, when complaints arise.

Notwithstanding some defects, medical opinion generally looks favourably on the Bill, and it is realised that it is the fruit of much pains and care on the part of the responsible Ministers.

Local Appointments in the Irish Free State

The Local Appointments Act, 1926, took from local authorities the power of appointing officers except on the recommendation of a central authority set up

INVESTIGATION OF INFECTIOUS DISEASE

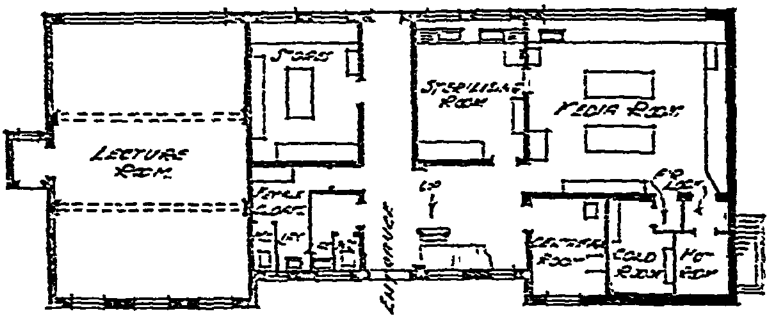
OPENING OF M.A.B. LABORATORY BY THE MINISTER OF HEALTH

In 1913 the Metropolitan Asylums Board appointed a research pathologist whose function should be to investigate the ætiology of infectious disease rather than to deal with immediate demands for preventive precautions. A laboratory was provided first at the Lister Institute and later at the National Institute of Medical Research, Mount Vernon, and work was continued under the general supervision of Sir German Sims Woodhead until his death in 1921, after which the Board invited a scientific advisory committee to exercise general supervision over its research and bacteriological laboratories. On the recommendation of this committee the Board in 1924 decided to make each hospital self-contained by the appointment of a skilled pathologist with a properly equipped laboratory at his disposal. As a first step two such laboratories have been instituted for the more special branches of pathological work and for research. A temporary building has been adapted at the North-Eastern Hospital to serve the needs of institutions in the North of London, whilst new laboratories have been erected at the Park Hospital, Hither Green, S.E., to form the southern group laboratory and to be the headquarters of Dr. J. E. McCartney, who in April of last year took up his duties as the Board's Director of Research and Pathological Services. On Monday last, May 9th, the new buildings at Hither Green were formally opened by Mr. Neville Chamberlain, Minister of Health, in the presence of a distinguished gathering.

Mr. Francis Morris welcomed Mr. Chamberlain on behalf of the Metropolitan Asylums Board, of which he is chairman. After referring to the misleading title under which the Board disguised its activities from the public he pointed out that it had over 8000 beds in hospitals for infectious diseases, and that when there was last an epidemic of scarlet fever and diphtheria the number of patients under treatment was 9300. This enormous amount of material gave a great opportunity for investigation and it was the Board's intention to carry out research on a larger scale. The problems of rheumatism in children and of encephalitis lethargica were being studied, but an even bigger problem was presented by measles. Whilst the type of scarlet fever seemed to be growing milder the virulence of measles was increasing. Taking the death-rate for the last 15 years it would be seen that of every million people dying 251 died from measles and only 42 from scarlet fever. As many as 35 000 cases of measles occurred among London school-children in one year.

Mr. Neville Chamberlain agreed that the name of the Metropolitan Asylums Board was not altogether enlightening; it was in fact difficult to dissociate it from some suggestion of dementia, although, of course, nothing could be more unfounded. Those who really knew were aware that the M.A.B. was the great public health hospital authority in London, having under its control about 28 different institutions. Huge as was this establishment it could not be said to be too large; last year, he believed, over 33 000 cases of infectious diseases were notified in London alone, excluding tuberculosis. Whilst the M.A.B. was known throughout the country as a model of what an authority should be in its provision for the isolation and treatment of these infectious diseases

PLAN OF LABORATORIES

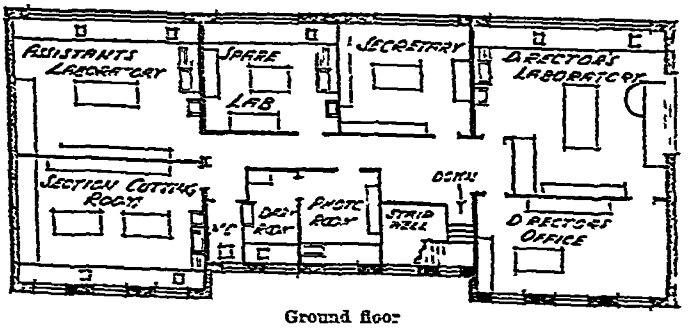


First floor

it could, he thought, be equally well acclaimed as a model of what administration could be. It must nevertheless remain a fact that the maintenance of all these hospitals was very expensive, and that, however economically it was done, its expense must substantially add to the burden of the rates.

There was another aspect of this economic question. He had been a manufacturer long before he was a politician, and he recollected that one of the objects constantly before the manufacturer was to try to find means of discovering flaws in raw materials before much time and money had been expended in converting them into finished articles. Not only had he to try to find means of avoiding the flaws but he had to dispense with what were called wasters. In human experience too there were wasters. He supposed that broadly speaking 5 per cent. of the children born in London died from an infectious disease before they reached the age of 20, and of those who survived an unknown percentage were crippled by having had these diseases. It was necessary to consider the waste caused by this premature death of people who could never make any contribution to the common life. All the care of their parents, all the education, the service of water, gas, light, recreation, and the rest of it—all this was to be spent on children who were going to die before they reached the age of 20, just as it had been spent on the others who were afterwards going to pay their contribution. If this could only be prevented there would be a substantial diminution in the burdens which the Board was bound to throw on the ratepayers of London.

When he thought of all the money spent on isolation hospitals and on treatment of infectious diseases, it seemed to him extraordinary that more had not been done to discover their cause and the means of their prevention. As a member of a public body years ago it had been his duty to inspect infectious hospitals. On the first occasion he had asked his guide what was the cause of scarlet fever.



Ground floor

scope, as Sir Humphry Rolleston made clear at the inaugural ceremony[1] In his report Dr G A Auden traces the history of the distribution of clinics showing how present needs are being met and provision made for future development, a short review is given of the charitable organisations which cooperate with the school service in rendering aid to ailing children In spite of expansion in every branch of remedial and preventive work the percentage of children requiring treatment remains high, no doubt many of the ailments are temporary or trivial, but their number is an indication of the need for commencing preventive and remedial measures before school entry

Some interesting observations are made in the dental section of the report Considering the greater activity and duration of sunshine in New Zealand and the undoubted greater richness of antirachitic factors in the average dietary there, Dr E H Wilkins was surprised to find a lower incidence of dental caries in Birmingham than in New Zealand He has now correlated the incidence of dental decay with that of rickets, as evidenced by bony deformity of the chest wall in children of the 5–6 year old group, and comes to the tentative conclusion that rickets predisposes to decay of the teeth

Discussing rheumatic infections in school-children, Dr. Auden estimates that 1 5 per cent of the elementary school population in Birmingham give evidence of heart disease, and Dr A P Thomson, by aid of an excellent map, shows the grouping of cases along the valleys of the Rea and the Hockley Brook It will be remembered that Dr F C Shrubsall found a similar grouping of rheumatic cases along the lines of the old watercourses in London The Children's Hospital is now acting as a sort of central bureau and clearing-house for all cases of rheumatism, working in cooperation with the Baskerville Home which has been enlarged to 90 beds

Dr Jessie J Stooke finds that left-handedness is present in Birmingham school-children in the proportion of about 1 to 36 and that it is almost twice as common in boys as in girls Dr Thomson's account of the special schools shows how closely associated these institutions are with the Children's Hospital, an excellent arrangement whereby provision for treatment is amply assured

Leamington

Dr W L Goldie deplores the large proportion of children (68 per cent) who are unvaccinated and the position is apparently becoming worse as the proportion of unvaccinated is even higher in the new entrants The dental work is rapidly increasing, the number reporting for periodical inspection at the clinic being over five times that of 1920, more of the dentist's time is given to treatment and less to inspection, while fillings have risen from 0 4 to 0 8 and extractions have fallen from 3 to 2 per child Except for the dental clinic and one for minor ailments the treatment of school cases is not carried out by the education authority directly, for the Warneford Hospital deals with tonsils and adenoids, defective vision, and ringworm cases This hospital also makes up for the absence of a complete orthopædic scheme by providing a well-equipped and up-to-date massage and electrical department Dr Goldie relates an interesting case of extensive developmental defect of bone involving especially the femora and gives an account of cardiac disease in a family affecting five out of eight children All these children were anæmic and undersized and had suffered from measles, scarlet fever, and whooping-cough, but not from rheumatism, such a condition might improve under an open-air regime, but unfortunately there is no open-air school or special school of any kind in the borough

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED APRIL 30TH, 1927

Notifications —The following cases of infectious disease were notified during the week —Small-pox, 277 (last week 358), scarlet fever, 1105, diphtheria, 671, enteric fever, 45, pneumonia, 1059, puerperal fever, 35, puerperal pyrexia 105, cerebro spinal fever 14, acute poliomyelitis. 11, acute polio-encephalitis, 1, encephalitis lethargica, 32, continued fever 1 dysentery, 9, ophthalmia neonatorum 146 No case of cholera, plague, or typhus fever was notified during the week

The cases of small-pox were notified from the counties of Cornwall 1 (Liskeard), Derby 8, Durham 121, Lancaster 2, Middlesex 8 (Hendon), Northumberland 15, Nottingham 2, Yorks North Riding 1, West Riding 62, Monmouth 57 The Hendon cases up to date number 9

Deaths —In the aggregate of great towns including London there was no death from small-pox nor from enteric fever 68 (0) from measles, 5 (1) from scarlet fever, 41 (11) from whooping-cough, 31 (11) from diphtheria, 51 (9) from diarrhœa and enteritis under two years, and 71 (18) from influenza The figures in parentheses are those for London itself Since this report was made up 5 of the cases of small pox reported from Hendon have proved fatal

SMALL-POX IN HENDON

We are indebted to Dr T S McIntosh, medical officer of health for the Hendon Urban District Council, for the following notes on the outbreak of small-pox there —

CASE 1 —Male aged 47, vaccinated in infancy Was comparatively mild case and is now convalescent Although this was not a severe case, it was not of the very mild type prevailing in certain parts of England at the present time

CASE 2 —Wife of Case 1, age 42, vaccinated in infancy Was a severe case, but I understand is now convalescent

CASE 3 —Daughter of Case 1, female, aged 16, unvaccinated Very severe case Confluent fatal case

CASE 4 —Daughter of Case 1, aged 8, unvaccinated A severe case, but doing well, and is expected to recover

Cases 5, 6 7, and 8 were workers in laundry to which linen from the family containing the first four cases was sent before the disease was recognised

CASE 5 —Female, aged 38, unvaccinated Very severe case Confluent, fatal

CASE 6 —Female, aged 15, unvaccinated Very severe case Confluent, fatal

CASE 7 —Female, aged 23, vaccinated in infancy Rapidly fatal case of hæmorrhagic small-pox This patient gave birth to a premature live child on the morning of the day on which the diagnosis was made The severity of the case is probably partly accounted for by the complication of pregnancy and parturition

CASE 8 —Female, aged 21, unvaccinated Moderate case Doing well and is expected to recover She was vaccinated after the onset of the first symptoms The vaccination was successful, the vesicles appearing about the same time as the small-pox eruption

CASE 9 —The new-born child of Case 7, female Developed papules a week after birth and died on the fifth day Was successfully vaccinated the vaccination vesicles appearing about the same time as the small-pox eruption

Dr McIntosh adds that the source of infection of Case 1 has not been traced

THE MEDICAL PROFESSION IN PALESTINE —At the recent conference in Jerusalem of the Jewish Medical Society of Palestine it was stated that there are now 510 physicians in Palestine, 373 being Jews, 10 Arabs, and 123 Europeans About one-third of the Jewish physicians are women

POST-GRADUATE MEDICAL TEACHING IN GLASGOW. The programme of the summer session has now been issued The teaching facilities comprise (1) a general medical and surgical course, (2) a certain number of special clinical courses, and (3) clinical assistantships The first is a whole-time course occupying the last two weeks of August and the first two weeks of September, and is arranged to interest general practitioners Clinical assistants are appointed for periods of three months, but their work need not necessarily occupy the whole day They will have facilities for intimate study of cases, under supervision, and for detailed investigation, but will not be permitted to treat patients Further information may be had from the Secretary, Glasgow Post-Graduate Medical Association, University of Glasgow

"Audi alteram partem"

LOCAL EPILEPSY

To the Editor of THE LANCET

SIR,—Dr Gordon Holmes's Savill Memorial Oration in your issue of May 7th makes me think that it will interest your readers to learn that Richard Bright, just upon a century ago, knew a good deal about local epilepsy

He says [1] —

> "As far as I have been able to infer from my own observation, I should say that the organic causes of epilepsy, connected immediately with the brain, are more frequently such as affect its surface, than such as are deep seated in its substance"

He then tells us that thickening of the skull or of the membranes, or a tumour on the surface of the brain will cause epilepsy, and he records cases in support of his contention He describes "the paralytic condition which remains after the attack," and he maintains that from the symptoms the situation of lesions in the cerebral nervous system can be foretold Particularly important in connexion with epilepsy is the case of a man who had fits of the right side Bright [2] says —

> "I now gave it as my opinion that these fits were owing to some local disorganisation affecting the membranes and cineritious portion of the brain on the left side
> My reason, then, for supposing that the epileptic attacks in this case depended rather on a local affection was the degree of consciousness which was observed to be retained during the fits"

Although he was aware of the value in diagnosis of retention of consciousness, yet the context shows that he knew that consciousness may sometimes be lost during fits due to organic disease

A second paper,[3] which shows that Bright knew where the lesion was in ordinary aphasia, concludes thus —

> "The symptoms which arise in cerebral and spinal disease are actually the results of the lesions which the different parts of the nervous system have suffered"

I think we may with justice say that Bright was one of the earliest enunciators of the doctrine of cerebral localisation

I am, Sir, yours faithfully,

May 8th, 1927 W HALE-WHITE.

TESTS FOR DRUNKENNESS.

To the Editor of THE LANCET

SIR,—I am not concerned with the differences of opinion as between Dr Southgate and Sir William Willcox on this question, but as a member of the committee which issued the report I am keen on accuracy It is no doubt an amusing pastime to set up Aunt Sallies and then to proceed to knock them down Unfortunately many of your readers—unacquainted with the details of the report—are not in a position to recognise the game

Dr Southgate says "that for the committee to announce as a test the smell of alcohol in the breath is unsound and utterly unscientific" When Sir William Willcox replies that the committee never pledged itself by any statement in its report to being able to find any smell in alcohol, and that the smell of alcoholic liquor in the breath was considered of value only as an indication that the person had recently consumed alcoholic liquor Dr Southgate calls the reply a quibble Then again, Dr Southgate asks for "the source of evidence which proved conclusively to the committee" that "in the performance of complex occupational acts such as the driving of a motor-car an experienced driver might be little affected by relatively large amounts of alcohol since his long experience of driving had caused his control of his car to become almost automatic" As the committee's report contains no such statement the question does not arise Possibly we shall be told that this reply also is a quibble

May one in return venture to ask Dr Southgate certain questions He writes, "surely it will be of service to the presiding magistrate to be able to state from a quantitative analysis of the urine that the accused must have taken at least so much alcohol" As the magistrate is concerned only with determining whether at the time of the event the accused was "drunk" (as defined by the committee in its report) of what value will it be to know this? Does Dr Southgate suggest that a certain well-defined concentration of alcohol in the urine can be taken as the index of being "drunk" for all persons at all times and under all circumstances? If so will he name this concentration, and will he say that a less concentration can be taken as the index of not being "drunk"? But if he is not prepared to do so, then wherein does he differ from the committee which considered this concentration inquiry was of "great value from a scientific point of view," but not to be practicable for the purpose of defining "drunk"?

I am, Sir, yours faithfully,

Hove, May 7th, 1927 E ROWLAND FOTHERGILL

MEDICAL DEFENCE

To the Editor of THE LANCET

SIR,—We are directed to request that you will kindly publish the following statement with regard to the circumstances in which the Council of either of the two English Defence and/or Protection Societies may be prepared to advise and/or defend and/or indemnify a member

Subject to the provisions of the Articles of Association the Council may on application from a member who is in benefit—

1 Advise on any matter connected with medical practice

2 Initiate or defend or assist in defending proceedings where a question of professional principle is involved

3 In the event of an adverse verdict, or of a settlement out of court, provide indemnity against damages and costs of the other side

4 Defend or initiate and carry through proceedings to vindicate a member's professional interests, honour, or character whenever they have been threatened or jeopardised

5 Defend and/or indemnify a member in proceedings brought against him in respect of the act or omission of (*a*) a partner who is a member of any other defence or protection society with whom a reciprocal arrangement has been entered into, (*b*) an assistant who is a member of any other defence or protection society with whom a reciprocal arrangement has been entered into, (*c*) an assistant not himself a member of any defence or protection society, provided that the member has paid an additional annual subscription of 10*s*, (*d*) a locum tenens, whether a member of any defence and/or protection society or not, (*e*) a subordinate medical officer, including a house surgeon or similar hospital medical officer, whether a member of any defence and/or protection society or not, (*f*) a non-medical assistant or subordinate, such as a nurse, dispenser, X ray operator, masseuse, or laboratory assistant, save in a case where in the opinion of the Council such non-medical assistant or subordinate was with the sanction of the member, whether express or implied, carrying out, (i) a duty which should only be undertaken by a medical practitioner, or (ii) without supervision a duty which should only be undertaken by a non-medical assistant or subordinate under the orders and direct supervision of a medical practitioner

We are, Sir, yours faithfully,

HUGH WOODS,
General Secretary,
The London & Counties Medical
Protection Society, Ltd,
Victory House,
Leicester square, W C

JAMES NEAL,
General Secretary,

[1] Reports of Medical Cases, 1830 ii, 514

[2] Guy's Hospital Reports 1836 i 9

[3] Guy's Hospital Reports, 1837, ii, 279

and, to his astonishment, had bowled him out first ball Even now it was impossible to be sure of its cause, some medical men believed that they had discovered the villain of the piece, whilst others thought that the wrong party was suspected There was still a great deal of research to be done to find out what really was the cause Although it might not be so mortal a disease as it was some years ago, nevertheless scarlet fever remained a great tax on our resources, the average stay in hospital of a scarlet fever patient was about eight weeks Those who were doing research on scarlet fever were turning out armies of anti-reds by way of reinforcements to the regular forces of the body, and if by so doing they could shorten, by even a week, the patient's stay in hospital, it would considerably relieve the accommodation for patients

A great deal of work had been done on diphtheria but there, he thought, the party had been arrested, found guilty, and convicted, and to-day, as a consequence, not only had the treatment of the disease materially improved, but advance had been made on a still more profitable course—we had begun to find out how to make people immune from the attacks of the disease We had been able entirely to prevent its incidence and to check and control it even in remote parts of the country As a result of all this the case-mortality from diphtheria in London had fallen from about 13 per cent at the beginning of the century to under 4 per cent at the present day He thought the results achieved against these two diseases were encouraging enough to show that money spent on the regular provision of facilities for research was a good investment The laboratory which he had just inspected was not particularly magnificent either in its appearance or its appointments, it was designed on strictly business principles But to the eye of imagination there were possibilities, and time would make it far more interesting than many a famous monument As the Minister responsible for the department whose chief duty was to try to reduce the necessity for any such Minister at all, he most heartily congratulated the Board upon its enterprise and on the infinite care and pains taken to ensure the success of the experiments that would be done Money had been spent on the things that really mattered

The Minister then declared the laboratories open and a vote of thanks was proposed by Canon Sprankling (Chairman of the Infectious Hospitals Committee) and Sir D'Arcy Power, a member of the Board

The visitors next proceeded to inspect the laboratories, over which Mr Chamberlain had previously been conducted by Dr McCartney.

The Laboratories and Their Work

There are two buildings and the cost of their erection and equipment was about £13,500 The larger, of which two plans are shown on page 1049, measures 87 feet long by 36 feet wide and contains a lecture room for the use of students attending the hospital's practice There are bacteriological, pathological, biochemical, and photographic sections, an internal telephone system links up all the main rooms, and binocular instruments have been secured where possible in order to reduce fatigue The smaller building, a short distance from the laboratory, is the animal house and has rooms for keeping stock animals, experimental animals, and fodder, for washing up, and for inoculations

The Scientific Advisory Committee to the Metropolitan Asylums Board consists of Dr F H Thomson (chief medical officer, Infectious Hospitals Service), Sir George Buchanan, Prof H R Dean, Dr C M Wenyon, Prof J C G Ledingham, Prof Hugh MacLean and Prof Major Greenwood The director and assistant director of research and pathological services are Dr J E McCartney and Dr William Mair, and the assistant pathologist is Dr V D Allison. Although the Scientific Committee recommended the present reorganisation of the Board's laboratories and is convened to discuss any large piece of investigation proposed, it will not suggest the line of work to be pursued

The Services.

ROYAL NAVAL MEDICAL SERVICE

Surg Comdrs W G Edwards and G C Cross are placed on Retd List with the rank of Surg Capt

Surg Lt-Comdr G W Woodhouse to be Surg Comdr

M L McCauley and L A. F Wiles to be Surg Lts

ROYAL NAVAL VOLUNTEER RESERVE.

Surg Lts G A Clark and R H O Robinson to be Surg Lt-Comdrs

ROYAL ARMY MEDICAL CORPS

Capts A E Richmond, T Young, J M Mackenzie, and R T Cox to be Majs

Capts H M Hart-Smith and J W Darling to be temp. Capts, and temporarily relinquish the rank of Capt

TERRITORIAL ARMY

Capt C D Walker resigns his commn and retains his rank

Capt R Ward to be Lt-Col and to comd the 128th (Wessex Fd Amb)

Capt J F O'Grady, from the Gen List, to be Capt

Lt L N Jackson, late R F A, Spec Res, to be Lt

Lts P Mumford and W H Gratrix, from the Gen List, to be Lts

Hygiene Companies —Capt J Cohen, from the Gen. List, to be Capt

The King has conferred the Territorial Decoration upon Lt-Col L A. Harwood and Maj W. F Mackenzie

ROYAL AIR FORCE

Flight Lt R S Topham is placed on the retired list at his own request

Flight Lt L Game is transferred to the Reserve, Class D2, and is employed with the Regular Air Force for a period of one year

INDIAN MEDICAL SERVICE

The King has approved the retirement of Lt-Col A F W King

ROYAL ARMY MEDICAL CORPS WAR MEMORIAL

A service of dedication of the stained glass window which completes the Royal Army Medical Corps War Memorial in Westminster Abbey will take place on Sunday, May 22nd, at 4 15 P M, in the nave of the Abbey No tickets of admission are required, but subscribers to the memorial fund and others interested desiring reserved seats for the 3 o'clock evensong preceding it should apply by letter to Major-General H B Fawcus, C M G, D S O, Room 313, War Office, Whitehall, S W 1 Uniform need not be worn at the service of dedication

---

EXTENSION OF HULL ROYAL INFIRMARY—It is proposed to provide an annexe to this hospital at a cost of £150,000 Mr Philip B Reckitt has given a site of 50 acres and £5000, and Mr T R Ferens, Sir H Gamman, the late Mr T Bailey, and Messrs Reckitt and Sons, Ltd, have each subscribed £10,000 Eventually 500 beds will be provided with all the necessary ancillary accommodation. Meanwhile a new operating theatre on the existing site is nearly completed and extensions of the out-patients' department and the nursing accommodation are in prospect

ROYAL SANITARY INSTITUTE—A Sessional Meeting will be held on Friday and Saturday, May 20th and 21st, in the Guildhall, Bath Dr Charles Porter will preside On Friday, at 7 30 P M., a discussion on Cremation will be opened by Dr H T Herring (hon secretary, Cremation Society of England), other speakers will include Dr Preston King, Mr J S Carpenter, and Mr G A Noble On Saturday, at 10 30 A M, Mr F P Sissons will read a paper on Sewage Disposal, and there will be a visit to the Bath City Sewage Disposal Works experience of the Home Office for many years had been and still was that licence holders as a body were willing and anxious to comply with the letter and spirit of the Act and to assist the Home Office in its administration While the Home Office agreed that it would be better to have more inspectors he could not hold out any hope in view of the need for economy that they would be willing to approach the Treasury for more money He thought that the inspections were carried out as well as they possibly could be in the circumstances He saw a letter in a newspaper not long ago from a distinguished scientific man, Prof Julian Huxley He referred to a reply made in the House of Commons by the Home Secretary from which it appeared that in the last 18 months the laboratories of University College were visited by an inspector 30 times without notice University College was specially singled out because he believed that there were more experiments carried out there than at any one place in the world That seemed to indicate a considerable amount of efficiency notwithstanding that the inspectors were somewhat short-handed Of course they had a great deal more to do than merely to inspect They had to be highly qualified persons who were able to give advice when applied to by schools which wished to carry out some very special piece of scientific work, and it would undoubtedly be a great benefit to the country not only in this direction but in many others if they could afford the money for increasing their number

Viscount **HALDANE** said he was chairman of the Vivisection Committee for some time and had the superintendence of the work that was done in the Home Office in connexion with the reports of the inspectors He was sorry to hear economy put up as a plea for not appointing more inspectors, even Lord Banbury would not invoke that sacred word But he comforted himself by this, that he did not think that an increase in the number of inspectors would make very much difference Lord Banbury was mistaken in supposing that the inspectors actually supervised the conditions under which the experiments were carried out That was not necessary Under the Act of 1876 a person could not perform an experiment unless he had a licence and that licence was not issued unless the inspectors were satisfied The great bulk of the work was paper work on the nature of the research to be made, and whether it involved pain The inspectors paid occasional visits in order to see that the conditions of the law were being observed He bore out from such experience as he had gained that there was very little violation of the Vivisection Acts in this country If there was any it was always heard of by responsible people and they stopped it The professors and persons concerned were very anxious not to have any scandal in connexion with the law So far from thinking that the Vivisection Acts did not go far enough he was not sure that they did not go too far It was only a few days since he saw a very distinguished young physiologist who had come to London to see him He asked him what brought him there, and he replied "There is an experiment which has to be made and should be made on a dog It is not at all serious, but it cannot possibly be made under an anæsthetic It involves taking out some of the spinal substance and some of the arterial blood and the observations must be taken without an anæsthetic There is only one way for it, and I have come up to be vivisected," and he was vivisected For several days he was in one of the hospitals, remaining in bed during part of the process He (Lord Haldane) mentioned that as showing that some of the experiments which were stopped by the Act were experiments which human beings with a desire for knowledge were ready to undergo He did not think that it was desirable that that should be extended A certain amount of experiment on animals was absolutely essential with the kind of diseases which existed to-day, requiring wholly new knowledge How such researches as those of Dr Banting on insulin could have been carried out without vivisection he did not know He was sure that some of the provisions of the Vivisection Acts went so far that although processes were quite painless they were hampered by the condition that anæsthetics must be strictly used and that the animal must not be allowed to live He said these things for the purpose on the whole of supporting the view taken on behalf of the Government He thought it would be a good thing to have another inspector of eminence but his work would be very largely paper work

Viscount **KNUTSFORD** said that everybody wanted to protect animals from cruelty, and if an addition to the number of inspectors would satisfy those who shared the sentiments of Lord Banbury, or would save them from the repetition of his speech every year, it might be worth the £2000 or £3000 a year which the Home Office said it would cost Lord Banbury had told the House about the vast number of experiments—as many as 209,000, but the removal of a flea from one dog to another was an experiment under the Act The 209,000 experiments did not all need an inspector One could not make any experiment on an animal except at a licensed place Lord Banbury said there were 242 licensed places He (Lord Knutsford) thought that the correct figure for England and Scotland was 267

Lord **BANBURY** said he was speaking of England and Wales

Viscount **KNUTSFORD** said that a great many of the places were in one building There were 68 of the 267 in London alone That being so a very large number of the licensed places could be visited in a few minutes He desired that the laboratories should be properly inspected, but two whole-time men could in the opinion of a great many people do the work perfectly well Two instances had been given of the way in which the law was broken One lady immersed some trout in polluted water she did not know that she had to get a licence for that The other irregularity was that a licensee holding a certificate " A " made simple inoculations into cats without authority Of course she had no business to do that, but those were the irregularities last year He thought that to appoint two more men at £3000 a year it would be a waste of money and he was glad that the Government did not intend to do it

Lord **DANESFORT** said he was not an antivivisectionist He realised that for purposes of research there were cases in which it was necessary to inflict pain upon animals but he felt very strongly that pain should never be inflicted except for purposes of research and under restrictions which while they did not unduly embarrass scientific work would avoid unnecessary pain to animals He would be very sorry to see the powers given by the Act of 1876 to vivisectionists extended Those who framed and passed the Act of 1876 intended the system of inspection to be a reality Notwithstanding the recommendation of the Royal Commission in 1912 that there should be four whole-time inspectors there were now only two Lord Knutsford thought that two were sufficient, but in his (Lord Danesfort's) opinion the weight of evidence was against Lord Knutsford's view

Lord **BANBURY** said Lord Desborough had admitted that breaches of the licence did occur, but he said they were not wilful, being due to ignorance The result, however, to the animal operated on was the same in either case That was one of the reasons why he thought there should be more inspectors and he trusted that the question of economy would not prevent the Home Office from adopting that course

HOUSE OF COMMONS.

WEDNESDAY, MAY 4TH

Herrings Treated with Dye

Mr **JOHNSTON** asked the President of the Board of Trade whether his attention had been drawn to recent instances where herrings treated with dye had been sold as kippers, whether he was aware that in one instance boxes of kippers coloured with dyestuffs were supplied to a Colchester retailer at *2s 4d* per box, and retailed by him at *12s 10d* per box, and what steps he could take to safeguard the public in this regard —Mr **GUINNESS** (Minister of Agriculture) replied I am aware that it is the practice of some curers to use dyes for improving the appearance of herrings sold as kippers, but there is no power to prevent this practice unless the colouring material used is injurious to health. With regard to the last part of the question the whole subject of the price of fish is now being investigated by the Food Council

Sulphur dioxide as Meat Preservative

Mr **HERBERT WILLIAMS** asked the Minister of Health whether his attention had been drawn to the decision of the Board of Health in Scotland to allow the use of sulphur dioxide as a preservative for minced butcher meat during the months of June, July, August, and September in any year, and whether, having regard to the higher average temperature in England and Wales, he would consider introducing the same regulations —Sir **KINGSLEY WOOD** (Parliamentary Secretary to the Ministry of Health) replied My right hon friend is aware of the decision of the Scottish Board of Health, but as at present advised does not propose to modify the regulations as issued in regard to meat

Prisoner Suffering from Encephalitis Lethargica

Mr **ERNEST BROWN** asked the Home Secretary whether his attention had been called to a case at the Central Criminal Court in which a victim of sleepy sickness was sent to prison with hard labour, although the judge thought the mother was right in saying that the prisoner required treatment not as a criminal but as an afflicted person, and whether he would consider this case with a view to the remission of the sentence —Sir **WILLIAM JOYNSON-HICKS** replied Yes, Sir, my attention has been called to this case. The prisoner in question is reported to have suffered from encephalitis lethargica in 1919, but he is not at present considered to be certifiable under either the Lunacy or the

THE EARLY TREATMENT OF CHILDISH AILMENTS.

To the Editor of THE LANCET.

SIR,—It may be of interest to your readers to learn that at the Royal Cambrian Institution for the Deaf and Dumb, with its 80 resident pupils, the average drug bill for the last seven years has not exceeded £10. Included in this amount are items for dressings, cod-liver oil, and syrup of hypophosphates, and although the amount is low the health-rate has been excellent.

I have been the honorary physician to this institution for 22 years, and consistent with the sound health of the pupils it is to my advantage to have as few calls as possible. Fortunately for me the matron realises that it is much easier to keep the children well than to cure them when ill; as a consequence she phones me at once as soon as any sign or symptom suggesting a departure from normal health makes its appearance. Taken at such an early stage most of the illnesses resolve themselves into something starting from the stomach, and in nearly every case a few doses of calcium permanganate or Condy's fluid brings about a termination of the embryonic gastritis. It is astonishing the readiness with which cases of feverishness rising to 103°–104° F. respond to the permanganate, in my opinion much more satisfactorily than they do to drugs of the salicylic group, especially as the latter nearly always leave some reactionary after-effect. In cases of inflamed pharynx the matron immediately swabs the throat with petrol, which has the effect of clearing away all evidence of spots or patches within three days. Externally petrol is applied to all cuts and scrapes, so as to wash away grease and the dirt bound up with it; on evaporation the wound is left clean and dry, and ready for a dry dressing. The early application of first-aid treatment of this sort is responsible for the infrequent appearance of impetigo.

Nearly all the children, whose ages vary from 6–16 years, come to the institution from local education authorities, with the result that most of the treatment is required at the beginning of a term, being devoted to counteracting the evil results of the holidays. One cannot help feeling that the school medical officers with their large staff of nurses might do more for these children whilst they are in their school districts during the holidays. The ignorance which exists as to the proper methods of educating children of this sort is immense, and visits by nurses and even by school medical officers would enlighten not the parents but the medical staff too.

I am, Sir, yours faithfully,

Swansea, May 4th, 1927. G. ARBOUR STEPHENS.

DALRYMPLE HOUSE: TREATMENT OF INEBRIETY.—We have received the combined report of the Homes for Inebriates Association and of Dalrymple House, Rickmansworth, which is managed by a committee of this body and which has now completed its forty-third year of successful treatment of drink and drug addicts. The profits are expended on improvements in the home, and no member of the Association benefits financially from the enterprise. At the end of last year 21 patients were in residence, 7 private and 14 under the Inebriates' Act, as against 12 and 9 respectively at the beginning of the year. Seventy were admitted and 69 discharged during the year under review. Of these only three were drug addicts, all medical practitioners. The superintendent, Dr. F. S. D. Hogg, lays stress on the evil results of drinking methylated spirit, and refers to recent work describing the legal precautions that have been found necessary in the United States. One of his patients was almost blind on admission from this cause, and another was mentally enfeebled—he fears permanently. Dr. Hogg does not give details of the treatment used, but appends a very complete analysis of a group of 1615 patients consecutively discharged. Of these 1119 left after the efflux of time, 31 because further treatment was unnecessary, the remainder from illness, private affairs, or unsuitability for treatment; 18 suffered from heart disease and 17 from kidney trouble. This appendix will interest all those concerned with the treatment of inebriety.

Parliamentary Intelligence.

HOUSE OF LORDS.

WEDNESDAY, MAY 4TH.

EXPERIMENTS ON ANIMALS.

Lord BANBURY asked the Government the number of inspectors appointed under the Cruelty to Animals Act, 1876. He said he did not wish to make any accusation or charge against the inspectors under this Act. He did not know who they were and he had no reason to doubt that they were doing their duty in a proper and efficient manner, if it was within their power to do so. Since he put this question down the Home Secretary, in answer to a question in the House of Commons, had said that there were two whole-time inspectors, and that the last occasion on which they had interfered in order to prevent an animal from suffering prolonged and agonising pain was on March 25th, 1926. He would like to ask the noble lord, who would answer for the Government, how he could justify the statement made by professors and doctors that there never was any cruelty at all, and that the inspectors might be trusted to carry out the Act, because there were humane people who in no circumstances whatever did anything contrary to the Act whether an inspector was present or not? How many places were licensed for the purposes of these operations? He gathered from the answer to another question in the House of Commons on April 11th of this year that 212 places had been licensed. There were only two inspectors to inspect those 212 places. In 1925, which was the last date on which returns from the Home Office had been given, there were 209,014 experiments. Of these 9402 were done with anæsthetics, and the balance of 199,612 were done without anæsthetics, and were, he presumed, injections or experiments of that nature, and therefore not calculated perhaps to cause any pain. He would point out, however, that these injections might be very likely after a time to cause intense suffering if disease was inflicted as a result of the injections. In regard to the experiments with animals under anæsthetics each inspector would have to inspect 4701 experiments in a year in 212 different places. In University College alone, according to an answer given in the House of Commons on Dec. 13th last, in the case of dogs only there were 114 experiments in two years. There were 574 animals experimented on in one year and only one class of animal was used, and yet the number of inspectors was only two. During the whole of his (Lord Banbury's) political career he had been an apostle of economy and he did not wish in any way to cause additional expenditure, but in a case of this sort, where the additional expenditure would probably not be more than £3000 or £4000 a year, he thought that it was necessary as long as these experiments were allowed that the Act of 1876, which specially insisted upon inspectors being appointed, should be carried out in a proper manner. No one could say that with the large number of experiments which were carried out, and with 212 places licensed, two men, however excellent they were, could possibly carry out their duties in a proper manner. The fact that last year one of these inspectors had to interfere because an experiment was not being carried out in a proper way showed that it was absolutely necessary that there should be an increase in their number.

Lord DESBOROUGH, replying for the Home Office, said that down to 1913 there were two part-time inspectors for Great Britain—Sir George Thane and Sir James Russell—who combined the work of inspection with that of other scientific posts which they held. In 1912 a Royal Commission was appointed and that Commission suggested that there should be four whole-time inspectors. In 1913 two whole-time inspectors were added to the existing two part-time inspectors. On Sir James Russell's death the number was reduced to three. Sir George Thane was nominally a part-time inspector, but during the last two years of service he gave practically the whole of his time to the work. When Sir George Thane retired in May, 1922, the staff was reduced to two whole-time inspectors, solely on the ground of the necessity for economy in public expenditure, which still continued. From the point of view of efficiency of administration a larger staff was desirable, and the Home Office agreed with his noble friend on that point. From the point of view of efficiency three whole-time inspectors would not be too many, and four would be still better. But he did not think that the point of view of Lord Banbury, who suspected violation or evasion of the law, need be seriously taken into account. Licence holders did sometimes commit serious breaches of the Act, or the conditions of their licences, but it was almost invariably due merely to negligence or to failure to understand a somewhat intricate and technical piece of legislation. Wilful evasion of the Act was practically unknown. On the contrary, the

TUESDAY MAY 10TH

The Health of the Army

Sir BASIL PETO asked the Secretary of State for War whether he was aware that the reports on the health of the army for 1923 and 1924 were only published in 1926, and whether he could take steps to see that the reports for 1925 and 1926 were published at an early date, and that, in future, these reports should be published within a reasonable time of the period to which they related —Sir L WORTHINGTON EVANS replied During the past two years special steps have been taken to bring the issue of these reports up to date and the reports for 1922 1923, 1924 and 1925 have all been published since the beginning of 1925, that for 1925 having been issued two months ago My hon friend will appreciate that the collection and collation of information and statistics from all parts of the world makes it impossible for publications of this kind to appear close on the period to which they relate

House Construction since the War

Mr TAYLOR asked the Minister of Health the total number of houses, whether subsidised or not, built each year in England and Wales since the war —Mr CHAMBERLAIN replied The following is a statement showing the number of houses completed during each year ended in March, since 1919 —

Year	With State assistance	Without State assistance	Total
1920	715	53,800 (*a*)	251,988
1921	28,549		
1922	101,071		
1923	67,853		
1924	18,664	67,546	86,210
1925	67,669	69 220	136,889
1926	106,987	66,439	173,426
1927 ..	153,779	64,200 (*b*)	217,979
Total	545,287	321,205	866,492

(*a*) Separate figures are not available for the years 1920–23, and the number is based partly on an estimate

(*b*) This figure includes an estimate of 33,000 for the half-year ended March 31st, 1927 Final figures for this half year are not yet available

Uses of Machine-skimmed Milk

Brigadier-General CLIFTON BROWN asked the Minister of Health (1) what are the principal articles of food for which imported machine-skimmed milk was used, and (2) whether the 88,000 tons of machine-skimmed condensed milk imported last year into this country was all used for human consumption, or whether some of it was used for other trade purposes, and, if so, for what purposes —Mr CHAMBERLAIN replied So far as I am aware, all the machine-skimmed condensed milk referred to was imported for human consumption, including various manufacturing and household uses I regret that I have no information which would enable me to state in detail the principal articles of food in which it is used

Meal Relief for Night Telephonists

Viscount SANDON asked the Postmaster-General whether night telephonists got an uninterrupted meal relief, and if accommodation was provided for rest, and, if not, whether he would take steps to provide these —Sir W MITCHELL-THOMSON replied In a large number of cases night telephonists have a scheduled meal relief on all-night attendances In other cases a meal relief could not be scheduled without bringing a relief officer on duty for a short period at an unreasonable hour but the calls during certain hours of the night are so infrequent that in practice the men can take meals without difficulty It is not considered necessary to provide special accommodation for rest, as night telephonists are paid for wakeful attention, and their weekly attendance is only 45 hours

---

MARRIED WOMEN MEDICAL OFFICERS—Durham County Council has decided to give three months' notice terminating the appointments of married women officers on its medical staff whose husbands are in receipt of adequate incomes

REBUILDING BRADFORD ROYAL INFIRMARY—It is hoped that the foundation-stone of the new infirmary will be laid in October The total cost of the building is expected to be £500,000, and the first instalment is to be a self-contained ward block which will cost £75,000 The site is in Duckworth-lane, on the outskirts of the city, and the late Mrs Harry Smith, who formerly lived on the site, has bequeathed a sum of about £15,000 to the institution An individual donor has promised £30,000, and a group of friends has made itself responsible for the building of a wing

Mental Deficiency Acts, he is, however, being kept under special mental observation in the prison hospital. All the relevant facts were before the learned judge when he decided to send the young man to prison, and after careful consideration I have come to the conclusion that I would not be justified in advising any remission of sentence

THURSDAY, MAY 5TH

London Police and First-aid

Mr DAY asked the Home Secretary how many small field-dressing outfits had been supplied to the mounted police in the Metropolitan police area for the purpose of first-aid, whether first-aid was also rendered where necessary to horses in the streets of London, what was the cost of these outfits, and on how many occasions they had been used to the last convenient date —Sir WILLIAM JOYNSON-HICKS replied No field-dressing outfits have yet been supplied but 300 dressings have been ordered It is proposed that mounted police shall render first aid where necessary to horses in the streets if the driver consents The cost is £12

Departmental Committee on Solicitation Laws

Dr SHIELS asked the Home Secretary if the proposed departmental committee on the solicitation laws would include Scotland in its sphere of inquiry, would Scotland be given representation on the committee, and, if that was not considered practicable, would a separate Scottish committee be appointed Sir PATRICK FORD asked a similar question —Sir WILLIAM JOYNSON-HICKS replied It is intended that the proposed inquiry should extend to Scotland and that a person residing in Scotland should be appointed to the Committee

Price of Parlour Houses

Mr HERBERT WILLIAMS asked the Minister of Health how the contract price for parlour houses now compares with the price before the announcement of the reduction of the subsidy —Mr CHAMBERLAIN replied The average price of parlour type houses included in contracts let by local authorities during the three months ended in March last was £490, as compared with an average price of £513 for the previous December quarter

Massage and Electrical Treatment for Insured Persons

Mr BOWERMAN asked the Minister of Health whether in view of the recommendation of the Royal Commission on National Health Insurance that massage and electrical treatment be added to the list of additional benefits, he would consider the desirability of promoting a scheme whereby such treatment might be obtainable without difficulty for insured persons if and when the treatment had been prescribed for them.—Mr CHAMBERLAIN replied In the event of massage and electrical treatment being added to the list of additional benefits, I should be prepared to give all possible assistance to approved societies, with the object of securing for their members the opportunity of obtaining the necessary treatment under satisfactory conditions and on reasonable terms I should, however point out that before any regulation could be made adding the treatment in question to the list of additional benefits, I should have to be satisfied that a reasonable number of societies desired to amend their existing schemes of additional benefits and to divert to massage and electrical treatment some of the money at present allocated to other treatment benefits

Medical Officer's Dispute with Local Authority

Mr JOHNSTON asked the Secretary of State for Scotland whether he was aware of the prolonged correspondence between the parish council of Strath, Skye, and the Scottish Board of Health relative to a dispute over the continuance of the present medical officer for the parish in his appointment and that the council had intimated its unanimous intention of resigning unless it was given freedom of action in terminating the present appointment and in securing possession of the house tenanted by the present medical officer for the parish and what steps if any, he proposed to take in the matter —Sir JOHN GILMOUR replied I am aware of the present circumstances of the medical service in the parish of Strath and have myself been in correspondence with the parish council in the matter By Section 3 (5) of the Highlands and Islands (Medical Service) Grant Act, 1913, the parish medical officer cannot be dismissed from his post without the consent of the Scottish Board of Health In pursuance of their duty under that section the Board ordered an inquiry into the medical service in this parish and appointed a senior member of the Scottish Bar as Special Commissioner for that purpose The Commissioner found that certain professional charges brought against the parish medical officer had not been substantiated and ought never to have been made, and also that there was no other ground on which his dismissal from the parish appointment would be justified After consideration of the Commissioner's report the Board decided that this was a case which clearly called for the protection afforded to parish medical officers in the Highlands and Islands by the section referred to, and I entirely concur in that decision

Small-pox at Hendon and Golders Green

Mr DAY asked the Minister of Health the total number of small-pox cases that had been reported from Hendon and Golders Green to date in the recent outbreak, the number of deaths resulting, and what, if any, special precautions had been taken to prevent any further cases occurring —Mr CHAMBERLAIN replied Eight cases have occurred in the Hendon Urban District which includes Golders Green, and four deaths have resulted As soon as the nature of the disease was determined all the usual preventive measures were adopted by the local authority, and a medical officer of my department has rendered assistance

MONDAY, MAY 9TH

School Medical Service

Dr VERNON DAVIES asked the President of the Board of Education the number of school-children examined at schools by the medical officers of the Lancashire education authority for each of the last seven years for which statistics were available, the number of medical officers employed in this work and the salaries and emoluments paid to these officers, and the average cost of medical services for each examination made —Lord EUSTACE PERCY replied The following is the information asked for —

Financial year	Medical officer staffs *	Estimate of total salaries in respect of School Medical Service	No of inspections (routines, specials, and reinspections)
		£	
1921–22	$15^{1}/_{5}$	15,765	74,246
1922–23	$15^{1}/_{5}$	16,528	79,823
1923–24	$12^{4}/_{5}$	13,315	80,927
1924–25	$12^{4}/_{5}$	12,239	71,538
1925–26	$13^{3}/_{5}$	13,167	67,465
1926–27	$13^{3}/_{5}$	13,087	†95,106

* Estimated equivalent of whole time officers engaged in School Medical Service work The work of these officers is not confined solely to medical inspection, but includes many other duties connected with the School Medical Service

† Includes special examinations of children in connexion with school feeding during the coal dispute

Comparable figures for the year 1920–21 are not available It is not possible to state the average cost of medical services for each examination made, as the school doctor's work includes many other duties connected with the School Medical Service besides medical inspection

Deaths from Small-pox

Lieut -Colonel HOWARD-BURY asked the Minister of Health how many deaths had been due to small-pox during the present year in this country —Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) replied Twenty-seven deaths among persons suffering from small pox have so far been reported in England and Wales during the present year, but in some cases the death certificates have not yet been received

Colonel HOWARD-BURY asked if the Ministry of Health were taking any steps, in view of the danger of an epidemic, to recommend vaccination

Sir K WOOD replied that they were doing all they could in that direction

Commander WILLIAMS asked if the Department were drawing the attention of the school authorities to the very great need of encouraging vaccination

Sir K WOOD said that the Department were doing all they could in that direction

Housing Schemes in Scottish Rural Areas

Mr SKELTON asked the Secretary of State for Scotland the number of local authorities in Scotland responsible for submitting schemes under the Housing (Rural Workers) Act, 1926, how many had submitted schemes, and how many such schemes had been approved by the Scottish Board of Health —Sir J GILMOUR replied Though the provisions of the Housing (Rural Workers) Act, 1926, apply particularly to rural areas any local authority may submit a scheme under the Act if they consider that within their area there are persons of the classes specified in the Act for whom approved accommodation should be provided Thirty-two local authorities in Scotland have submitted schemes and 28 of these schemes have been approved by the Scottish Board of Health

THE new Science School attached to Clifton College will be opened on Thursday, June 2nd, by the Prince of Wales

Sir David James Galloway M D Edin has been reappointed an unofficial member of the Executive Council of the Straits Settlements

KENT COUNTY MENTAL HOSPITAL —On Tuesday, June 7th, at 2 30 P M., Princess Mary Viscountess Lascelles will open the nurses' home at this hospital at Maidstone

WEST KENT MEDICO-CHIRURGICAL SOCIETY —At a meeting to be held at the Miller General Hospital Greenwich, to-day (Friday), May 13th at 8 45 P M, Dr H- Nockolds will give a presidential address on the Poor-law Hospital and its Relation to General Practice

THE MEDICAL PRAYER UNION —The annual medical missionary breakfast of the Medical Prayer Union will be held on Wednesday, May 18th, at the Refectory, University College, Gower-street, W C 1, at 8 A M, under the presidency of Dame Mary Scharlieb An address will be given by Dr Katherine Harbord of Jaunpur India. An intimation of intention to be present will be welcomed by the hon secretary, Dr Tom Jays, Livingstone College, Leyton, E 10

BEDS FOR RHEUMATIC CHILDREN IN LONDON Under the arrangement made between the Metropolitan Asylums Board and the London County Council, beds are now available at Queen Mary's Hospital, Carshalton, and Highwood Hospital, Brentwood for the accommodation of children under 16 years of age who are suffering from acute rheumatic fever, subacute rheumatism, the later stages of acute rheumatism, rheumatic chorea and rheumatic carditis including recurrent attacks Medical practitioners who desire to recommend child patients for admission should communicate with the School Medical Officer, County Hall, London, S E 1 giving particulars of the cases The accommodation is reserved for children resident in the County of London

RUTHERFORD MORISON TESTIMONIAL FUND —This fund shows a final available balance of £1206, after the payment for the portrait of Prof Morison and sundry incidental expenses have been met This sum has been handed over to the council of the University of Durham College of Medicine, as trustees, to administer the Rutherford Morison Travelling Scholarship, which was the purpose selected by Prof Rutherford Morison for the balance of the fund Prof Morison desired that the scholarship should be available for candidates proposing to take the degree of Doctor of Surgery (D Ch.) in the University of Durham, and particularly to enable such candidate to undertake six months' surgical study abroad Each scholarship is to consist of the accumulated annual income of the trust fund for three years, the first award to be in 1929

The nominating board for the scholarship is to consist of the Professors of Surgery, Anatomy, Physiology, Pathology and Bacteriology for the time being in the University of Durham College of Medicine and one member of the Honorary Medical and Surgical Staff of the Royal Victoria Infirmary

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION —On Tuesday, May 17th, at 10 A.M., Dr B T Parsons-Smith will give a special demonstration at the National Hospital for Diseases of the Heart; on Thursday, May 19th, at 1 P M., Mr. Maurice Whiting will give a special demonstration at the Royal London Ophthalmic Hospital, and on Friday, May 20th, at 2 P M., Mr Maynard Smith will give a surgical demonstration at St Mary's Hospital These demonstrations are open to members of the medical profession without fee From May 16th to 28th a special course will be held at the Infants Hospital under the direction of Dr Eric Pritchard This course will be of particular interest to the infant welfare worker For the general practitioner the Hampstead General Hospital staff will undertake a course from 4 30 to 6 P.M. for two weeks from May 16th. A ten weeks' course in neurology began on May 9th at the National Hospital, Queen-square, it is divided into three parts, any of which may be taken. The Fellowship can arrange for practical courses in anæsthetics and obstetrics, and also make arrangements for clinical assistantships in gynæcology During June there will be special courses in Diseases of the Chest at the City of London Hospital for Diseases of the Heart and Lungs (Victoria Park), Diseases of Children at the Children's Clinic; Gynæcology at the Chelsea Hospital, and Ophthalmology at the Central London Ophthalmic Hospital. The Fellowship also provides a general course at the associated hospitals Copies of all syllabuses and of the *Post-Graduate Medical Journal* may be had from the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1

ON Monday next, at 8 P.M., Mr. Lionel G Pearson, F R I B A., will read a paper before the Royal Institute of *British Architects on the subject of Foreign Hospitals* The address of the Institute is 9, Conduit-street, London, W 1

MILK-SUPPLY AT WORKINGTON —According to Dr R W Macpherson, medical officer of health for the Borough of Workington, tests of milk retailed in the borough revealed that 75 per cent of the milk was dirty, the deposit in unsatisfactory samples consisting mostly of cow dung, hairs, and dirt

STOBHILL HOSPITAL GLASGOW —The Glasgow Parish Council continue to develop this institution on the lines of a fully equipped modern hospital At an estimated cost of about £40,000 a medico-electrical department is in course of being provided This department, when completed, will supply the latest developments for the treatment of diseases by means of electricity

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH —A quarterly meeting of the College was held on May 3rd, Dr G M Robertson, the President, in the chair Dr John Robert Lord and Dr William Bell were introduced and took their seats as Fellows of the College and Dr Walter Duncanson Chambers was elected to the Fellowship

The following were elected members of the College Arthur Mills, Harold Edward Whittingham Ram Swarup Gupta, James Davidson, James Alexander Law Loudon William Lindsay Kinnear, and Raymond Leopold Albert Kitchen

Dr R A Fleming was nominated a representative on the Conjoint Committee of Management of the Triple Qualification The Parkin Prize was awarded to Dr J D Comrie The Freeland Barbour Fellowship was awarded to Dr T R R Todd

Pathology (New Regulations)—F B Mallinson, St George's

INSTITUTE OF HOSPITAL ALMONERS —At a meeting to be held at the Grotrian Hall, Wigmore-street, London, on Thursday, May 26th, at 5 P M, the subject of Hospital Social Service will be discussed by Dr A C E Gray, Sir John Rose Bradford, F R S, Sir Berkeley Moynihan, and Sir Arthur Stanley

UNIVERSITY OF LONDON —The first report of Mr T Franklin Sibly, D Sc as principal officer of the University, has just been issued During the year 1926-27 the total number of candidates for all examinations was 33,220 as against 32,353 last year, the total number of successful candidates was 13,224 compared with 13,275 last year Various benefactions and changes in the organisation of teaching are recorded those referring to the medical schools have already been noted in our columns

University College—An address on Lord Lister and the Romance of Surgery will be given by Mr Raymond Johnson in the Botanical Theatre of University College, on Monday, May 23rd, at 5 30 P M Dr A M H Gray will preside

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—Mrs Christabel Burton has given £4000 to this medical school to found a scholarship in memory of her mother, Mrs Geraldine Harmsworth, who died in August, 1925

ROYAL SOCIETY OF ARTS —On Wednesday, May 18th, at 8 P M, an address on Industrial Welfare in Great Britain and the United States will be delivered by Mr Robert R Hyde, Director of the Industrial Welfare Society

Dr W J O'Donovan has been appointed physician in charge of the skin department of the London Hospital on the retirement of Dr J H Sequeira, who has been appointed consulting physician

Dr. Chisholm Williams, of Finchley, has been made an allowance of £120 a year by the trustees of the Carnegie Hero Fund As a result of radiological work which continued from 1895 until last year Dr Williams has lost his right hand and two fingers of his left hand

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION —A meeting of this Association will be held at 11, Chandos street Cavendish-square, London, W 1, on Friday, May 20th, at 5 P M (tea 4 30 P M), when a discussion on Swimming Baths will be opened by Dr J Graham Forbes, Dr F W Alexander, and Mr F E Wilkinson

GRANT TO QUEEN CHARLOTTE'S HOSPITAL —The committee of this hospital, which, as we announced last week, is appealing for £250,000, has been informed that in recognition of the national importance and urgency of the task which it is undertaking, the Ministry of Health has sanctioned a *special grant of £15,000 for* the hospital's maternity and child welfare work

ABERDEEN UNIVERSITY CLUB, LONDON —The next bi-annual dinner will be held at the Piccadilly Hotel on May 26th at 7 30 P M Lord Cecil of Chelwood will take the chair and the guest of honour will be Mr John Buchan M P Any graduates of the University, men or women who wish to attend the dinner or join the club are asked to communicate with Dr Anstruther Milligan at 11, Upper Brook-street, W 1

RONTGEN SOCIETY —The annual general meeting will be held on Tuesday, May 17th, at 8 15 P M, in the British Institute of Radiology, 32, Welbeck-street, London, W, when Dr R G Canti will describe an investigation into the effects of beta and gamma radiation on normal and malignant tissue cells growing in vitro, by means of the cinematograph with demonstrations, and Prof J A Crowther will give an analysis of some observations on the action of X rays on drosophila eggs

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE —The 97th annual meeting is to be held at Leeds from August 31st to Sept 7th under the presidency of Sir Arthur Keith F R S, the subject of whose address will be Darwin's Theory of Man's Descent as it Stands *To day Particulars of the programme* may be had from the Secretary of the Association at Burlington House, London, W 1

INSTITUTE OF PSYCHO-ANALYSIS — On Friday evenings at 8 30 P M Dr Ernest Jones is giving a series of lectures at the London *Clinic of Psycho-Analysis*, 36, Gloucester place, W 1, on the Relation Between Psycho-Analysis and General Medicine It is proposed to devote from half to three-quarters of an hour to discussion and questions at the close of each lecture The fee for the course will be 30s to medical practitioners, or 15s to medical students, and tickets may be got from the Hon Sec, Dr John Rickman at the Clinic

LEBANON HOSPITAL FOR MENTAL DISEASES —The twenty-eighth annual meeting of this hospital will be held at Friends House, Euston-road (opposite Euston Station), London, on Thursday, May 19th, at 3 15 P M (tea at 1 30) Dr E W G Masterman will preside and Dr H Watson Smith, director of the hospital, will personally present his report on the year's working Amongst the other speakers will be Major J W Mackinnon, R A M C Dr Francis Edwards, and Lieut -Colonel H G L Wortabet I M S All who are interested are invited to attend The general secretary of the hospital is Miss Hilda Fox, and the London Office is at 130, Marylebone road, W 1

SOCIETY OF MEDICAL OFFICERS OF HEALTH A meeting of the Maternity and Child Welfare Group of this society will be held at the Shoreditch Model Welfare Centre 210 Kingsland-road on Wednesday afternoon May 18th, when cases will be shown by the medical officers of the Shoreditch Maternity and Child Welfare Department The meeting will begin with tea at 4 30 P M, after which cases will be shown At 5 15 P M Dr Glen Davison will read a paper entitled the Newcastle-upon-Tyne Caloric Percentage Method of Dieting the Premature and the Sick Infant

Heald—Central London Throat, Nose and Ear Hospital, Gray's Inn-road, W C Intensive course London Lock Hospital, Dean street, W Clinical course of instruction throughout the month—Maudsley Hospital, Denmark Hill, S E Special course continuing throughout the month in Psychological Medicine—Infants Hospital, Vincent square, S W Afternoon course Special lectures and demonstrations Hampstead General Hospital Haverstock Hill, N W Special course for General Practitioners 4 30 to 6 p m Medicine, surgery, and the specialties Further information from the Secretary

NORTH-EAST LONDON POST GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N

Monday, May 16th—2 p m, Medical Cases in the Wards 2 30 p m to 5 p m, Medical, Surgical, and Gynæcological Clinics Operations

Tuesday—2 30 p m to 5 p m, Medical, Surgical, Throat, Nose, and Ear Clinics Operations

Wednesday—2 30 p m to 5 p m, Medical, Skin, and Eye Clinics Operations

Thursday—11 30 a m Dental Clinic 2 30 p m to 5 p m, Medical Surgical, and Ear, Nose and Throat Clinics Operations

Friday—10 30 a m, Throat, Nose, and Ear Clinics 2 30 p m to 5 p m, Surgical, Medical, and Children's Diseases Clinics Operations 4 30 p m, Special Demonstration on Selected Cases of Nerve Diseases by Dr L R Yealland

KING'S COLLEGE, Strand, W C

Tuesday, May 17th—5 p m, Prof R J S McDowall Autonomic Nervous System (Third of four free lectures)

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN, Hunter street, W C

Monday, May 23rd—5 30 p m, Prof H Beckwith Whitehouse The Menstrual Function (Second of three free lectures)

ROYAL NORTHERN HOSPITAL, Holloway-road, N

Tuesday, May 17th—3 15 p m, Dr W R Reynell Demonstration of Medical Cases

INSTITUTE OF PATHOLOGY AND RESEARCH, St Mary's Hospital, W

Thursday, May 19th—5 p m, Lt-Col S P James, (I M S retd) Some Methods and Problems of Malaria Research

LONDON SCHOOL OF DERMATOLOGY, St John's Hospital, 49, Leicester-square, W C

Tuesday, May 17th—5 p m, Dr H MacCormac Treatment of Syphilis (1)

Thursday, 5 p m, Dr K N G Bailey Pathology Demonstration

LONDON HOSPITAL MEDICAL COLLEGE, Mile End, E

Thursday, May 19th—4 15 p m, Prof Knud Faber Gastritis Its Relation to Achylia and Ulcer (Schorstein Lecture)

UNIVERSITY COLLEGE, Gower street, W C

Tuesday, May 17th—5 30 p m, Mr W H McLean (late Sudan Government Services) National, Regional and Town Development Planning

MIDDLESEX HOSPITAL MEDICAL SCHOOL, Berners-street, W

Monday, May 16th—5 p m, Mr John Fraser Some Surgical Problems

Tuesday—5 p m (Second lecture)

Wednesday—5 p m (Last lecture)

GUY'S HOSPITAL MEDICAL SCHOOL, London Bridge, S E

Friday, May 20th—5 30 p m, Prof E H Kettle Inflammation and Infection (First of four free lectures)

MANCHESTER ROYAL INFIRMARY POST GRADUATE COURSE

Tuesday, May 17th—4 15 p m, Dr D Dougal New Methods in the Investigation of Sterility

Friday—4 15 p m, Mr A H Burgess Demonstration of Surgical Cases

UNIVERSITY OF SHEFFIELD POST GRADUATE CLINICS

Tuesday, May 17th—3 30 p m (at the Jessop Hospital) Mr King Bleeding at the Menopause and After

Friday—3 30 p m (at the Royal Infirmary) Mr Cuff Clinical Cases

Appointments.

Durbridge, H, L R C P Lond, M R C S, has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Matlock District of the County of Derby.

Vacancies.

Births, Marriages, and Deaths.

BIRTHS.

Langwill—On May 5th, at Marloes road, Kensington, W the wife of Archibald Langwill, M D, F R C S E, of a daughter

Tothill—On May 2nd at Caa an righ, Leigh on Sea, the wife of Dr Henry Tothill, of a son

Walton—On May 3rd, the wife of John Walker Walton, F G S, L D S Eng, Tower House, 16, Manor road, Folkestone, of a son

MARRIAGES

Babington—Watts—On May 7th, 1927, at St Paul's Church Cliftonville Margate by the Rev Herbert Pegg, Vicar, Major J W H Babington, M D, I M S (retd) to Gladys Mary Joan Watts, M B, B S, daughter of the late Lieutenant Colonel J L Watts, R E, 25, Cornwall gardens Cliftonville

Dix—Vernon—On Thursday, May 5th, at the Church of St Mary the Virgin, East Barnet, by the Rev F A Overton, Victor W Dix F R C S, to Nan, youngest daughter of Mr and Mrs W A Vernon, of Bohun Lodge, East Barnet

DEATHS

Brown—On May 8th, at "Holmlands," Mornington road Leytonstone, Henry Havelock Brown, M B, C M, aged 69

de la Cour—On May 8th at St Leonards on Sea, after a short illness George Francis de la Cour, M D Edin, M R C S, L R C P, in his 84th year

N B—A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages, and Deaths

Harveian Lecture

ON

DIVERTICULA OF THE ALIMENTARY CANAL

Delivered before the Harveian Society on March 10th

By SIR BERKELEY MOYNIHAN, BART
K.C.M.G., C.B., LL.D.,
PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

A DIVERTICULUM is a wayside shelter by a main path. In the alimentary canal it is caused by a protrusion of the mucous membrane, with or without the other coats, from the lumen of the bowel In the embryo the extrusion of the wall of the intestine is an integral step in the formation of several of the organs whose processes are associated with, and essential to the work carried on in the digestive tract The liver and the pancreas arise as buds from the intestinal wall But not all the little pouches which spring from the mucosa have this full development We may discover the following different destinies

DESTINIES OF THE EMBRYONIC DIVERTICULUM

1. The diverticulum may develop in fœtal life and proceed on its normal career and lead to the growth of—

(*a*) The appendix whose connexion, throughout its whole length is fully maintained, there being no differentiation into a duct.

(*b*) The liver and pancreas whose connexion is maintained with the alimentary canal through their ducts

(*c*) The thyroid gland, whose connexion as a rule is completely broken in early fœtal life. The lumen of the protusion, from which this gland develops, does not go deep into the solid bud which consists of cells forming the thyreoglossal tract. The foramen cæcum on the dorsum of the tongue presents the upper and only patent part of this diverticulum; the pyramid of the thyroid gland is the remnant of the lower part of the tract. From the intervening portion of the tract, if obliteration is not complete, "dermoid" cysts may arise, they lie sometimes in the base of the tongue, sometimes below the hyoid bone whose development disintegrates the tract

2 The diverticulum may develop normally in fœtal life, but its connexion with the mucosa in the adult may remain only in curtailed condition, or may finally disappear

(*a*) The pouch of Rathke, seen in early infancy, vanishes as a rule completely in the course of a few years

(*b*) The diverticulum of Meckel found towards the lower end of the ileum is the unclosed portion of the omphalo-mesenteric duct.

3 The diverticulum may develop, and in normal circumstances disappear in fœtal life In a few instances this normal atrophy and disappearance may not take place, and a diverticulum is found in the adult Lewis and Thyng,[34] and also Keibel and Mall,[31] have shown that diverticula from the stomach, duodenum, and jejunum are frequently found in fœtal life and at their tip little solid masses of cells are seen, identical with the cells from which the pancreas grows These cells normally wither and are absorbed It would seem as though a whole series of efforts were made to develop the pancreas only those connected with the ducts of Wirsung and Santorini surviving The *others are there* in case of mischance. In a few such cases the normal disappearance does *not* occur and gastric, duodenal or jejunal buds, with an accessory pancreas attached to each may persist into adult life

FORMS OF DIVERTICULUM.

Various forms of diverticulum occur and may be classified in this way —

(*a*) A diverticulum which arises as a bud from the wall of the alimentary canal during development will contain all the coats of the bowel at that point It is said to be "congenital" in origin and "true" in structure.

(*b*) A diverticulum which occurs after development is complete, and is due to some abnormal process, will be found to contain, as a rule only the mucous coat, with or without an adventitious fibrous layer; in no case does it display all the coats of the alimentary canal It is "acquired" in origin and "false" in structure

(*c*) An acquired diverticulum may be caused either by the pushing out of the mucosa from the lumen owing to increased intestinal pressure, or by the dragging out of the wall by the adhesion of some firm structure to the outer side of the bowel. In the former case it is a "pulsion diverticulum," in the latter a "traction diverticulum" (Rokitansky[50]) A diverticulum, caused by the traction of an adherent structure to the outer side of the alimentary canal, as, for example, in the œsophagus, may enlarge because of the pressure of *increasing quantities of retained substances* within its cavity Beginning as a "traction diverticulum," its enlargement is due to conditions similar to those which create and enlarge a "pulsion diverticulum" A third form of diverticulum, the "traction-pulsion" diverticulum, may therefore be described

The following are the morbid changes which may occur in diverticula —

1 Inflammation in and around the sac; diverticulitis and peridiverticulitis
2. Suppuration
3 Sloughing and gangrene.
4 Perforation { to the surface
to a serous cavity, pleural or peritoneal,
to another viscus
5 Adhesions which lead to the compression and withering of the sac obsolescence, or, in the case of Meckel's diverticulum, adhesions leading in one or other way to intestinal obstruction.
6 Development of carcinoma
7. Rotation of the sac when it has grown to such a size as to develop a "neck" or pedicle, this rotation together with the pressure of the distended sac, causing obstruction.

Diverticula of the Pharynx

There are three forms of pharyngeal diverticula There is a high lateral form, which contains air and an accumulation of mucus; it is due to a lack of fusion between the branchial clefts, and the opening, as a rule very small, lies close to the tonsil Defects in the closure of branchial gaps are by no means infrequent; I have had many cases in which fistulæ and cysts in the neck have existed since birth; sometimes they communicate with the pharynx and then removal presents a nice occasion for the exhibition of care and *patience Cases are recorded by* Birtwistle and Frazer[6] Excess in activity in closure of the clefts is indicated by the development of little red pimples near the ear and on the neck When the failure to close a cleft affects the mucous rather than the cutaneous side a "blind internal fistula" develops which, under pressure forms at last a large cavity in which mucus is retained . it may be inflated by air. Food does not often enter, for in the act of deglutition the small orifice is closed. The first case was recorded by M Watson[62] of Manchester. The aerocele was found in the *dissecting-room It extended* from the tendon of the digastric muscle to the interclavicular notch The position of the opening into the pharynx just behind the tonsil. between the lower jaw above and the stylo-hyoid ligament below, pointed to some failure in the closure of the first postmandibular visceral cleft Kostanecki[34] has dealt fully with the subject of anomalies in connexion with the branchial clefts. Wheeler[64] recorded a very remarkable case in which a large aerocele was traced to its origin in the right sinus pyriformis After removing it a pharyngeal diverticulum of the kind presently to be described was found. and that too was removed Godlee and Bucknall[18] recorded a case of inflatable diverticulum extending from above the angle of the jaw to the clavicle The narrow pedicle passed through the thyrohyoid membrane. *They review* nearly 200 cases of pharyngeal pouches and fistulæ The exact nature of their own case has been questioned by Irwin Moore.[42]

A *second form of diverticulum* (often spoken of erroneously as "œsophageal") *springs* from the back of the pharynx, in the middle line, as a rule, but sometimes *at the* side, extends almost invariably to the left side (only in rare examples to the right

NATIONAL BABY WEEK COUNCIL

THE annual report for 1926 records a busy year in the Council's various departments. The demand for films was nearly three times as great as in the previous year; competitions for teachers and school children attracted 1500 entries, as compared with 600 in 1925, and the requests for help in organising local campaigns was larger than at any time since the war. An important sign of the Council's influence is seen in the fact that its regulations for the conduct of baby shows and competitions, which insist on the judges being medical practitioners, are being more and more widely adopted. The fourth English speaking conference, held at the Caxton Hall in July, was the principal feature of the London celebration of Baby Week and served to focus attention on special topics selected for discussion. During the week, through the courtesy of the Royal Society of Medicine a display of propaganda films was given in the Barnes Hall. The subjects chosen by the Council this year for particular emphasis are —

(1) Atmospheric Pollution in Relation to Maternity and Child Welfare.

(2) Development of Dental Clinics and Dental Care for Mothers and for Children under Five.

(3) The Home in Relation to Maternity and Child Welfare.

A silver challenge shield for the best Baby Week campaign, to be competed for by any part of the Empire except the British Isles has been presented by the *News of the World*. The Astor shield was won in 1926 by Northampton, and the William Hardy shield for areas with a population not exceeding 10,000, by Halesowen. The *Daily News*, which last year gave prizes for the greatest percentage reduction in neonatal mortality in districts with a population of not less than 50,000, is this year offering similar awards for the most efficient infant welfare centres, the judging to be carried out by the Baby Week Council. The Council itself is again holding competitions for teachers and school-children, particulars of which will be announced during Baby Week, to be celebrated, as usual, in the first week of July.

ELECTRARGOL IN PANDEMIC INFLUENZA

WRITING in a recent issue (March 13th, 1927) of the *Concours Medical*, Dr. Gidon points out that the key to the polymorphism of the secondary reactions of the influenza patient is found in the diminution or suppression of the specific defensive secretions so that the specific immunity of the organism may be temporarily annihilated by the toxin. Hence he urges the value of non-specific anti-infective medication, such as the intravenous administration of collargol or electrargol; with the latter he has obtained very satisfactory and constant results. He maintains that these are not wholly due to shock, but mainly to selective fixation of the product in the star-cells of Kuppfer in the liver, where two-thirds of the silver is retained. Extracts of liver six hours after electrargol injection have been shown by Duhamel to have quadrupled the organ's anti-streptococcic power, whether the drug is introduced intravenously or intramuscularly. The method appears to have a sounder pathological basis than many remedies advocated and is worthy of an extended trial if we are again visited by a serious epidemic of influenza.

DIETETIC PRINCIPLES

PREVIOUS pamphlets issued by the Health Service Bureau of the Wesleyan and General Assurance Society, Birmingham, have been favourably commented upon in these columns, and a recent set of four on the whys and hows of diet reach the same high standard of accuracy and simplicity. No. 1 is introductory and lays down certain general principles; by itself it may be a little bewildering, but it is presumed that the four pamphlets are issued together. Next follow two on what our foodstuffs consist of. Proteins, fats, carbohydrates, and roughage are dealt with in the first of these, and salts, water, and vitamins in the second. Rather too much space is spent on salts, and it is surely inaccurate to say that "rickets is due to a deficiency of calcium," particularly when oatmeal is mentioned in the next line as a source of this metal. There are certain forms of diet sometimes given to children in which the more oatmeal added the worse the rickets produced. The fourth pamphlet is entitled "a square meal," and the familiar diagram, first devised by Prof. Plimmer, is reproduced without acknowledgment, a page of explanation being added. The points here criticised are the only ones to which exception can be taken, and they are mentioned because the Health Service Bureau has a reputation for attention to detail which it is hoped it will maintain. Local authorities and others engaged in the task of educating the public in matters of health can be strongly advised to make use of these new pamphlets.

"THE COUNTRYMAN"

AN illustrated review makes its appearance this week, published by J. W. Robertson Scott from Idbury, Kingham, Oxford, and entitled "The Countryman" (2s. 6d.). It is a quarterly publication, forming a miscellany dealing with country life and progress, and it is proposed in its pages to provide practical information in connexion with every department of rural welfare. In the first issue we find contributions from (among others) Lord Ernle, the late Minister of Agriculture, and Sir Daniel Hall, Chief Scientific Adviser, Ministry of Agriculture and Fisheries, and in subsequent numbers we are encouraged by the editor to expect similar brief but authoritative essays aiming to inform the increasing number of citizens who are striving for better conditions of rural life. It is recognised by the large number of doctors who practise in the country that an intelligent view of country life would be of great value to the nation, and we wish the new magazine good fortune.

BEARDLESS SURGEONS

To the Editor of THE LANCET

SIR,—In reference to the story of the burnt whisker in THE LANCET, April 30th, p. 955, I would remark that it was not the nurse but the beardless surgeon who, after a sigh of concern said "Let us spray!" As stated under the "Beardless Vogue," I am still of opinion that the general order for the shorn face followed on the cult of Listerism; the technique of that system in 1881 was by no means perfect, however, as many operating surgeons—including Lister—wore whiskers, and others beards, and equally the ideals of ritual in aseptics later were difficult of attainment, as the following incident will show. Sole visitor to a provincial hospital in 1923, "well equipped in instruments, rubric, and fair linen," to see bone-plating by a London surgeon, I was bidden don overalls and rubber sandals, and stand on a floor flooded with antiseptics. After the play of a multipolar catherine wheel with a herculean task before him, and the patient "under," the clean-shaven, unmasked surgeon began by describing a circle with his extended arm and saying "Silence, touch me not!" Arduous and prolonged, the procedure became dramatic, when drilling and driving home the three tibial screws, *avec force majeure*, and perspiring freely, he himself broke the silence by calling for a 'kerchief and bidding me clear the dew-drops from his brow. It was summer time when in four and a half months the plate was removed and in due course aseptics triumphed over "those pernicious beings whose anchor is the meanest particle of the inconstant air."

I am, Sir, yours faithfully,

HERBERT A. SMITH

Ealing, W., *May 2nd, 1927.*

MIDWIFERY AMONG THE POOR OF LONDON

THE excellent results obtained, both in hospital and on the district, by the staff of the East End Mothers' Lying In Home, are by now well known, and the report for the last two years just issued, shows that they have in no way failed to maintain their own high standard. In a total of 4291 deliveries, all unselected cases, there was no instance of Cæsarean section or embryotomy; forceps were applied on 53 occasions only and 8 labours were induced. Of these all had normal puerperiums save one forceps case where there was a slight rise of temperature. Three babies died as a result of delivery—one an anencephalic and one a 28-weeks' child for which labour was induced because of bicornuate uterus and transverse presentation.

In the hospital there were 35 cases of maternal pyrexia, estimated on the B.M.A. standard. Of these 14 were due to general conditions and 8 to sapræmia. On the district there were but 13 morbid temperatures, only two of them being due to sapræmia. Even so these temperatures were down again in 48 hours except in one case of sapræmia and one of pleurisy. The rate of morbidity works out at 1.7 per cent. for the two years. The medical officer attributes the lower percentage on the district to the segregation of patients and the fact that primiparæ and bad cases would naturally be found in greater numbers in the hospital. So few were the cases of clinically contracted pelvis that no table is given to illustrate them. While improved midwifery no doubt partly accounts for this, it is also just about time that the reduction of deformities from rickets as a result of infant welfare work began to show itself among child-bearing women.

During the whole period under review there was only one case of eclampsia, in a primigravida who had suddenly developed albuminuria at the end of her time; she had a normal delivery. Two patients died in 1926 in hospital; one developed pelvic cellulitis after a difficult forceps delivery, whilst the other died after manual removal of the placenta. The babies do as well as the mothers; of the 1100 born in the hospital only 13 lost weight before discharge and 11 died. A maternal death-rate during ten years of 0.60 per 1000 in the slums of London constitutes a record that must be hard to beat.

observed. Pressure upon the neck, or a backward movement of the head brings food back into the pharynx, even after it has been swallowed A swelling is noticed on the left side, filling as the meal is taken, and sometimes growing so large as to resemble a thyroid tumour. Gas developing in the pouch escapes into the pharynx, and has produced in patients of my own a condition which I have not seen described, but which is perfectly characteristic, indeed pathognomonic. As the patient talks, the movements in the neck cause an expulsion of gas from the pouch, and the words spoken have "bubbles" in the middle of them, or among them; there is a curious, but quite unmistakable, spluttering of air in and among the spoken words This phenomenon may be produced in a very striking manner if the patient is asked to read continuously while a gentle pressure is exercised upon the neck. Dysphagia may sometimes be severe, and dyspnœa, cyanosis and coughing are caused by inhalation of particles of food suddenly expelled from the pouch into the pharynx Enlargement of the pouch may cause displacement of the œsophagus and may exercise such pressure upon it that food cannot be taken in quantities adequate to sustain life. Death may occur from starvation, or from inhalation pneumonia

Treatment—If the nature of the condition is explained to an intelligent patient he can often be made to control the condition quite satisfactorily. He must empty the pouch after each meal and wash it out with fluid drunk freely at the end of the meal, and preferably after the solid food has all been pressed back into the pharynx If the sac is already large it is best to remove it This was first accomplished by von Bergmann [5] in 1890 and in England by Butlin [9] Formidable difficulties and dangers chiefly derived from infection of the wound are said to attend this method. Before operation a day or two must be given to the toilet of the pouch to clean it After the sac has been cleared from its firm adhesions the whole wound is smeared with warm melted vaseline which is given time to "set," so as to seal off the connective tissue spaces The same method of closure of the stump of the excised pouch is used as is found so satisfactory in the case of the duodenum after gastrectomy. With these little precautions and careful methods no anxiety need be felt In all cases it must be made quite certain that any œsophageal obstruction, or any spasm of the crico-pharyngeus, is *overcome* The division of the operation into two stages, the pleating of the unopened sac, or its suspension from the highest part of the wound so as to invert it and make the entrance the lowest instead of the highest part, are not methods which I have felt either need or desire to practise Nor have I practised the method [30] in which the œsophagoscope is used to clean out the exposed sac and to facilitate its exposure and removal It is wise to feed the patient for many days after operation by a Jutte tube passed through the nose If the patient's strength is greatly depleted he may be fed in this manner for two or three weeks before operation and the other means of resuscitation with which we all are familiar be practised. *Gastrostomy* has been performed in several cases; the use of the Jutte tube makes this unnecessary

Diverticula of the Œsophagus

These pouches are found chiefly in two places—at or near the bifurcation of the trachea and at the lower end of œsophagus within one or two inches of the diaphragm When they occur in the former position they very rarely have any clinical importance; they may perhaps be a cause of mediastinitis as Rokitansky [40] supposed and they may at times cause slight intermittent dysphagia They are produced (*a*) by the traction of adherent bands springing from tuberculous and often calcified glands, and because of their position are known as "epibronchial" diverticula. These bands, "Ribberts [47] bands,' often very firm and strong are attached at the one end to the anterior wall of the gullet at the other to a gland which is often adherent to the trachea or the left bronchus Movements of deglutition and of respiration cause traction, hour by hour and day by day, until a little pouch is formed, which, perhaps by lodgment of food, but chiefly by continued traction, is steadily enlarged As Waggott [61] first showed the fundus of the pouch is in many cases, drawn to a higher level than the orifice, so that food is not able to lodge in the cavity (see also Riebold [44]) They may also be caused (*b*) by the protrusion of the œsophageal wall above "Lütgert's ledge" [39] This is a ledge found on endoscopic examination of the gullet; it lies near the tracheal division, and is often assumed to be due to the pressure of the left bronchus The ledge however, does not lie quite in the position of this bronchus nor is its direction the same, and the bronchus does not normally come into a relation with the œsophagus intimate enough to indent it. The ledge, however caused may have the effect of causing a temporary halt in the descent of large particles of food. A little bulging of the wall, so caused, may by degrees increase until a little pit and, finally, a fossa, is formed. If this explanation is sound the diverticulum is of the "pressure" variety In this situation the pouches rarely attract notice, they are sometimes seen on radiological examination but I have no experience of treating them

"Epiphrenic" diverticula, arising within a short distance of the diaphragm, and enlarging to a size which makes their recognition a simple matter for the radiologist, are attracting increasing attention I have seen three cases of this kind In one occurring in a woman the pouch was large, on the left side, shown clearly in the X ray photograph, and was associated with a high degree of cardiospasm. This has been noted in cases recorded by Hurst [28] and by Vinson [59] I found it necessary to do what is so rarely necessary, to dilate the cardia after gastrostomy My fingers passed easily into the diverticulum, which was as large as a lawn tennis ball My other two cases occurred in men and were unsuspected until X ray examination revealed the condition. In both cases the use of Hurst's tube relieved the symptoms of "dyspepsia" which had been attributed to a gastric ulcer. When the diverticula are large and causing symptoms an operation may be necessary Clairmont [14] has excised such a diverticulum and has kindly given me photographs of the case before and after operation. The result was excellent. In other cases operations have been practised for the anastomosis of the pouch with the fundus of the stomach, as first suggested by Lotheissen.[37] Gosset[20] described and illustrated a new operation of lateral œsophago-gastrostomy. The occasional presence of a stricture lower down in the œsophagus, possibly even of malignant disease, must be remembered.

Diverticula of the Stomach

They are very rare and are found in two places near the œsophageal opening and near the pylorus There is I think little doubt that two forms occur, the true and the false—the true being congenital, the false associated with penetrating gastric ulcer

The earliest recorded case is that of Weichselbaum.[63] The diverticulum was near the pylorus, and at its tip was a nodule the size of a hempseed, having the structure of the pancreas (see earlier reference to Lewis and Thyng)[36] There was also an accessory pancreas the size of a bean on the anterior duodenal wall Horrocks and Falconer [26] recorded the case of a man of 54, who died after a self-inflicted gunshot wound There was a marked constriction in the middle of the greater curvature said by Cunningham to be spasmodic A diverticulum arose from the pyloric canal on the greater curvature. There was also a pouch in the duodenum just beyond the pylorus. The floor of the gastric pouch was formed by an accessory pancreas Keith [32] has dealt with this subject also.

The diverticula arising in the proximal part of the stomach are always in close relation to the œsophageal opening. Keith points out that the stomach in the immediate neighbourhood of this opening is weak, side), and may form a large sac which, when distended, produces a prominent swelling in the neck, or extends even into the thorax

The first mention of this condition in surgical literature is found in the form of a letter from Mr Ludlow,[38] surgeon at Bristol, to Dr William Hunter The case was observed in the year 1764 and is described as one of "preternatural dilatation of, and bag formed in, the pharynx" The illustrations are excellent, and the accuracy of the description both of symptoms and of morbid anatomy is most remarkable The specimen is in the Hunterian Museum at Glasgow, and a drawing of it recently made for me shows how accurate were the original pictures In 1811 Monro,[41] of Edinburgh, described these pouches and discussed the method of their formation Sir Charles Bell [4] described a "preternatural bag formed by the membrane of the pharynx which impeded the introduction of a bougie," and gave a good illustration He was the first to suggest the origin of these protrusions in a spasmodic stricture of the muscle at the lower part of the pharynx, which caused fasciculation of the muscular layer above the obstruction, and hernial protrusion of the mucosa He commented upon the analogy with the sacculation of the bladder in urethral obstructions Matthew Baillie [2] relates a good example of this condition *Mondiere [40] is often quoted as recording an example of it.* Reference to his article, however. shows that it describes a case of perforation of the "lower part of the œsophagus" by a foreign body, a piece of granite, the size of a small apple, weighing 2 oz, which the patient "amused himself with, by rolling it in his mouth some moments before going to sleep" The condition is not very infrequent, but is no doubt often overlooked Zenker [65] says that it is "so rare that few physicians have ever seen a case" There are now few hospital surgeons without some experience of it

An interesting matter concerns the point of origin from the pharynx It was commonly asserted, as first by Zenker, that the origin is "at the boundary between the pharynx and the œsophagus" where the musculature was weak This area has since been described as the "Lannier-Hackermann" area by many writers, including the very last The search for "Lannier" results in the discovery that he is Laimer,[35] a former prosector in Graz, and "Hackermann" is Karl Haeckermann,[23] now of Bremen, whose thesis appeared in 1891 The "Laimer" area is triangular and lies below the *inferior constrictor*, on the posterior wall at the very origin of the œsophagus It is true that the wall of the gullet here is weak, but it is certainly not here that the pouch originates Waggett and Davis [60] have shown that this area, whose muscular wall is not so thick as in the rest of the œsophagus, does not yield when a stream of water is forced under pressure into the pharynx and œsophagus "When the dissected œsophagus was subjected to water pressure by attaching one end to the tap and securing the other there was a uniform dilatation of the œsophagus below and above the circular and sphincter portion of the inferior constrictor The circular fibres of the constrictor appeared as a waist belt, and no weakness could be demonstrated on the wall of the œsophagus immediately below the inferior constrictor"

When a specimen is examined in the post-mortem room, and the finger passed down from the pharynx into the œsophagus a very decided difficulty is experienced in overcoming the resistance of the sphincter guarding the entrance to the gullet This ring of muscle, of great strength, is formed by the crico-pharyngeus It is the obstruction offered by this sphincter which causes the pharyngeal wall to yield to pressure, and the protrusion of the mucosa begins immediately at its upper border, where a considerable deposit of fat between the muscular fibres is often seen The neck of the pouch therefore lies between the middle oblique fibres, and those lower circular fibres of the inferior constrictor which are now called the crico-pharyngeus A few oblique fibres may lie below the opening of the pouch

The origin of the third form—the lateral diverticulum—is, I think, quite different A lateral diverticulum is not a median diverticulum gone astray If the pharynx is dissected from behind a rather large pad of fat is found at the upper part of the œsophagus on each side immediately below the border of the crico-pharyngeus muscle If this pad is gently teased away a gap will be revealed between the lowermost fibres of the crico-pharyngeus and those fibres of the œsophagus which are descending from their origin at the back of the cricoid cartilage Advantage is taken of this hiatus to permit the passage of the recurrent laryngeal nerve with a branch of the inferior thyroid artery and vein, and a bundle of lymphatic vessels Here, indeed, is the weakest spot in the muscular armature of the pharynx or œsophagus, and, therefore, it is here that one would expect to find a pouch developing Though I have never had the opportunity of dissecting a specimen of lateral diverticulum there can be little doubt from the appearance shown in the drawings and descriptions of the only two whose records (Butlin [8] and Chevalier Jackson [30]) I can discover that this is their point of origin Butlin illustrates a case of lateral diverticulum, the specimen is now in the museum at St Thomas's Hospital Mr Urquhart, the curator, writes to me (March 8th, 1927):

"The opening of the pouch, I should say, had primarily been situated below the constrictor muscle, but as time passed the upper edge appears to have atrophied the lower fibres of the muscle to a small extent The opening into the pouch is some half-inch in diameter"

In some accounts, of which Bilton Pollard's [44] may be quoted as an exemplary instance, the pouch is said to spring from the œsophagus "below the inferior constrictor muscle", yet a careful reading makes it certain that the sphincter formed by the crico-pharyngeus was below the opening of the pouch

"On passing the forefinger into the œsophagus a resistance was encountered at its commencement There was no stricture in the ordinary sense and the mucous membrane appeared quite normal But nevertheless the commencement of the œsophagus was firm, not dilatable, and would only admit the first phalanx of the fore-finger Immediately above the resistant ring at the upper end of the œsophagus was the weak point in the middle line behind, at which the pouch had been developed"

There are therefore two forms of diverticulum in this region, a posterior median one passing through the interval between the oblique and the transverse *fibres of the inferior constrictor* (the fibres now described as the crico-pharyngeus muscle) as first shown by Killian [33]; and a lateral one passing through the weak spot, through which the recurrent laryngeal nerve enters They are both pressure pouches It is exceedingly probable that incoördination between the inferior constrictor fibres engaged in the propulsion of the bolus of food and the circular fibres which should relax to allow of the entrance of the bolus into the upper gullet, is responsible for the origin of the diverticulum but what causes this incoordination ? In a few cases a definite obstruction is found, due either to a spasm affecting the crico-pharyngeus, or to an organic stenosis lower down in the œsophagus Rarely this obstruction is malignant It is important *to remember the possibility of stricture* in the gullet when treatment is to be adopted

In one of Chevalier Jackson's [30] cases two diverticula were present Both were removed separately by operation one recurred and was again removed In the median form the lower lip of the opening (Killian's lip) is full, thick, and pouts into the pharynx in such manner that a bougie entering from the mouth is, like the food, easily deflected into the pouch The pouch as it enlarges extends to the left, and downwards even into the chest, into which perforation has occurred Robinson [49] records a case in which the pouch extended laterally and upwards "to the base of the skull" On distension it made the neck resemble that "of a pouter pigeon" The symptoms produced are characteristic Dysphagia is intermittent and progressive Regurgitation of unaltered food at once, or after many hours, or even days, is soon observed Pressure upon the neck, or a backward movement of the head brings food back into the pharynx, even after it has been swallowed A swelling is noticed on the left side, filling as the meal is taken, and sometimes growing so large as to resemble a thyroid tumour Gas developing in the pouch escapes into the pharynx, and has produced in patients of my own a condition, which I have not seen described, but which is perfectly characteristic, indeed pathognomonic As the patient talks, the movements in the neck cause an expulsion of gas from the pouch, and the words spoken have "bubbles" in the middle of them, or among them, there is a curious, but quite unmistakable, spluttering of air in and among the spoken words This phenomenon may be produced in a very striking manner if the patient is asked to read continuously while a gentle pressure is exercised upon the neck Dysphagia may sometimes be severe, and dyspnœa, cyanosis and coughing are caused by inhalation of particles of food suddenly expelled from the pouch into the pharynx Enlargement of the pouch may cause displacement of the œsophagus and may exercise such pressure upon it that food cannot be taken in quantities adequate to sustain life. Death may occur from starvation, or from inhalation pneumonia

Treatment—If the nature of the condition is explained to an intelligent patient he can often be made to control the condition quite satisfactorily He must empty the pouch after each meal, and wash it out with fluid drunk freely at the end of the meal, and preferably after the solid food has all been pressed back into the pharynx If the sac is already large it is best to remove it This was first accomplished by von Bergmann [5] in 1890, and in England by Butlin [9] Formidable difficulties and dangers, chiefly derived from infection of the wound, are said to attend this method Before operation a day or two must be given to the toilet of the pouch to clean it. After the sac has been cleared from its firm adhesions the whole wound is smeared with warm melted vaseline which is given time to "set," so as to seal off the connective tissue spaces The same method of closure of the stump of the excised pouch is used as is found so satisfactory in the case of the duodenum after gastrectomy With these little precautions and careful methods no anxiety need be felt In all cases it must be made quite certain that any œsophageal obstruction, or any spasm of the crico-pharyngeus, is overcome The division of the operation into two stages, the pleating of the unopened sac, or its suspension from the highest part of the wound so as to invert it and make the entrance the lowest instead of the highest part, are not methods which I have felt either need or desire to practise Nor have I practised the method [30] in which the œsophagoscope is used to clean out the exposed sac and to facilitate its exposure and removal It is wise to feed the patient for many days after operation by a Jutte tube passed through the nose If the patient's strength is greatly depleted he may be fed in this manner for two or three weeks before operation, and the other means of resuscitation with which we all are familiar be practised Gastrostomy has been performed in several cases, the use of the Jutte tube makes this unnecessary

Diverticula of the Œsophagus

These pouches are found chiefly in two places—at or near the bifurcation of the trachea, and at the lower end of œsophagus, within one or two inches of the diaphragm When they occur in the former position they very rarely have any clinical importance, they may perhaps be a cause of mediastinitis as Rokitansky [50] supposed, and they may at times cause slight intermittent dysphagia They are produced (*a*) by the traction of adherent bands springing from tuberculous and often calcified glands, and because of their position are known as "epibronchial" diverticula These bands, "Ribberts [47] bands," often very firm and strong, are attached at the one end to the anterior wall of the gullet, at the other to a gland which is often adherent to the trachea or the left bronchus Movements of deglutition and of respiration cause traction, hour by hour and day by day, until a little pouch is formed, which, perhaps by lodgment of food, but chiefly by continued traction, is steadily enlarged As Waggott [61] first showed, the fundus of the pouch is in many cases, drawn to a higher level than the orifice, so that food is not able to lodge in the cavity (see also Riebold [48]) They may also be caused (*b*) by the protrusion of the œsophageal wall above "Lutgert's ledge" [39] This is a ledge found on endoscopic examination of the gullet, it lies near the tracheal division, and is often assumed to be due to the pressure of the left bronchus The ledge, however, does not lie quite in the position of this bronchus, nor is its direction the same, and the bronchus does not normally come into a relation with the œsophagus intimate enough to indent it. The ledge, however caused, may have the effect of causing a temporary halt in the descent of large particles of food A little bulging of the wall, so caused, may by degrees increase until a little pit, and, finally, a fossa, is formed If this explanation is sound the diverticulum is of the "pressure" variety In this situation the pouches rarely attract notice, they are sometimes seen on radiological examination but I have no experience of treating them

"Epiphrenic" diverticula, arising within a short distance of the diaphragm, and enlarging to a size which makes their recognition a simple matter for the radiologist, are attracting increasing attention I have seen three cases of this kind In one occurring in a woman the pouch was large, on the left side, shown clearly in the X ray photograph, and was associated with a high degree of cardiospasm This has been noted in cases recorded by Hurst [28] and by Vinson [59] I found it necessary to do what is so rarely necessary, to dilate the cardia after gastrostomy My fingers passed easily into the diverticulum, which was as large as a lawn tennis ball My other two cases occurred in men and were unsuspected until X ray examination revealed the condition In both cases the use of Hurst's tube relieved the symptoms of "dyspepsia" which had been attributed to a gastric ulcer When the diverticula are large and causing symptoms an operation may be necessary Clairmont [14] has excised such a diverticulum and has kindly given me photographs of the case before and after operation The result was excellent In other cases operations have been practised for the anastomosis of the pouch with the fundus of the stomach, as first suggested by Lotheissen [37] Gosset [20] described and illustrated a new operation of lateral œsophago-gastrostomy The occasional presence of a stricture lower down in the œsophagus, possibly even of malignant disease, must be remembered

Diverticula of the Stomach

They are very rare and are found in two places, near the œsophageal opening and near the pylorus There is, I think, little doubt that two forms occur, the true and the false—the true being congenital, the false associated with penetrating gastric ulcer

The earliest recorded case is that of Weichselbaum [63] The diverticulum was near the pylorus, and at its tip was a nodule the size of a hempseed, having the structure of the pancreas (see earlier reference to Lewis and Thyng) [36] There was also an accessory pancreas the size of a bean on the anterior duodenal wall Horrocks and Falconer [35] recorded the case of a man of 54, who died after a self-inflicted gunshot wound There was a marked constriction in the middle of the greater curvature, said by Cunningham to be spasmodic A diverticulum arose from the pyloric canal on the greater curvature There was also a pouch in the duodenum just beyond the pylorus The floor of the gastric pouch was formed by an accessory pancreas Keith [32] has dealt with this subject also

The diverticula arising in the proximal part of the stomach are always in close relation to the œsophageal opening Keith points out that the stomach in the immediate neighbourhood of this opening is weak, and will yield readily under pressure The continuous vomiting of pregnancy as suggested by Hurst [29] may, in some cases, be responsible for the protrusion of the mucosa in consequence of the great and repeated sudden increase of pressure In the pig a large diverticulum is normally found near the cardiac orifice It is the analogue of the fundus of the stomach in man

Åkerlund [1] has recently drawn attention to the subject by the record of four cases diagnosed, radioscopically, during life All the patients were women, all had symptoms suggestive of gastric ulceration, in all the pouch was near the cardiac orifice, had a rounded, smooth surface, and retained an opaque meal for a few hours My friend, Dr Thomson, of Wakefield, has had a similar case, and has kindly given me the radiographs of it I have twice found during operations for duodenal ulcer a pouch on the greater curvature of the stomach about the size of a walnut, the exterior was smooth and free from adhesion, the finger readily entered the cavity, and in the floor of each an island of pancreatic tissue was present In one patient upon whom I performed gastrectomy for a tumour causing a pouch on the greater curvature of the stomach a smooth cavity was found, at the fundus of which was an adenomyoma [56] False diverticula associated with ulcer are, of course, very frequent and are well known They are the ' accessory pockets " formed when an ulcer penetrates deeply into the pancreas or into the liver, or into a mass of adhesions formed from the omenta

Possibly true diverticula are more common than we suppose Radiologically they must be difficult to distinguish from the false variety Hurst believes that—

> " The remarkable position, even outline, uniform rounded shape, free mobility, both with the stomach and to a slight extent independently of it, and the absence of tenderness make the diagnosis of a diverticulum of the stomach easy when the existence of such a condition is recognised, though in the absence of such recognition a diagnosis of ulcer would appear to be inevitable in spite of the very unusual features observed with the X rays "

Treatment —When a diverticulum lying near the cardia is large and causes symptoms it may be treated in the manner suggested by Hurst Large draughts of water fill the diverticulum, which may then be emptied by placing the patient in such a position that the orifice is the lowest part The pouch is washed out daily, or oftener If a pouch in the neighbourhood of the pylorus proves troublesome it may be treated by gastrectomy

Diverticula of the Duodenum

A case described in the year 1710 by Chomel [13] is often quoted as the first in which a duodenal diverticulum was observed The pouch contained 22 yellowish-white stones, and was probably an abscess in the head of the pancreas which had ruptured into the bowel In Alexander's translation of Morgagni's [43] letters there is a description of a case on which also doubts have been cast, which I do not share The first indisputable description was given in 1815 by Fleischman [17], in this country Habershon [22] was the earliest observer Very little clinical interest was taken in the condition until Case [10] first demonstrated a series of cases at a meeting of the American Medical Association in 1913, and in a later paper carried his discoveries further E I Spriggs [54] in this country, in a series of papers, also called attention to their significance As a result of radiological examinations we know now that the condition is not very uncommon, though more often overlooked than recognised Case,[11] in a consecutive series of 6847 examinations after a barium meal, found duodenal diverticula in 85 cases (1 2 per cent), and colonic diverticula in 138 cases (2 per cent) In 78 duodenal cases the pouch was solitary Even on the operation table, when we know from the X ray appearances that a pouch is present, it is not always a simple matter to recognise it at once I owe the knowledge I possess of this condition chiefly to Spriggs He has shown [55] that in 1000 consecutive examinations of the alimentary canal by X ray, 38 patients had 51 diverticula of the duodenum, situated as follows in the first part 1, in the second part 30, in the third part 16, in the terminal part 4; 20 patients were men, 18 women Case found in his series that the diverticulum was in the first part of the duodenum in 17 cases, in the second part in 49 cases, in the third and fourth parts in 19 cases He says that—

> " In about half the cases we may expect the diverticula to arise from the second portion of the duodenum, with the fundus of the sac lying within the substance of the pancreas or dorsal to it "

The condition may be congenital or acquired. The majority of the pouches are on the inner side of the second part of the duodenum, in the concavity which embraces the head of the pancreas The pouches often burrow into the gland, and they are generally free from any sign of inflammation At the fundus, as with the gastric diverticula, masses of pancreatic tissue may be discovered

Ulceration of the parts of the duodenum, from which the pouches commonly spring, is exceedingly rare The passage of the common duct obliquely through the duodenal wall is held to weaken it, and so to make easier the protrusion of the mucosa through this part The inspection of the pouches in the second part of the duodenum, during life and in the post-mortem specimens, makes me feel extremely doubtful as to their congenital origin, it is apparently certain that this condition is rare in youth and comparatively common in aged people Simmonds [52] has found diverticula in the first part of the duodenum in early childhood and concludes that these at least are congenital. I have seen only one case of this kind on the operation table, the walls of the pouch seemed to contain all the coats, the mouth was wide, there was no trace of inflammation, there was a fibrous mass at the fundus which I supposed was an aberrant pancreas The case was one of cholelithiasis, and the pouch had no connexion with the symptoms Huddy,[27] in an excellent discussion, decides in favour of the acquired origin of most examples The " pouching " of the first part of the duodenum associated with ulceration, and first described by Perry and Shaw,[44] is, of course, a very common condition, and has no affinity with the diverticula now considered There are probably both congenital and acquired diverticula, the congenital being associated with an accessory pancreas involving the first portion of the gut, the acquired involving the second part chiefly, and being perhaps induced by muscular deficiency near the ampulla The symptoms of duodenal diverticula are generally ascribed to a different cause I have operated upon several patients in whom this condition, previously diagnosed or quite unsuspected, has been found

Cholecystitis and duodenal ulcer are likely to be diagnosed when a diverticulum is the cause of the symptoms Now that we are becoming increasingly aware of the disease, and when almost every case is examined radiologically, mistakes will be less frequent The diagnosis cannot, I think, be made from the clinical history, but only on radiological examination It is by no means always necessary or even possible to treat the cases surgically A change of position will often allow a pouch to empty, paraffin will keep it lubricated and help to restrain putrefaction, and a large dose of bismuth carbonate taken once or twice weekly and allowed to remain in the pouches will probably help to keep infection away In 18 cases treated by Spriggs [55] 13 were completely relieved by medical treatment I have once excised a pouch about one and a half inches long and half inch in diameter from the outer side of the second part of the duodenum, and I had once pleated one into the duodenal wall Stiles has related to Spriggs a case in which he removed a pouch the size of a hen's egg, which sprang from the concavity of the duodenum and contained masses of pancreatic tissue in its wall Gastro-enterostomy when the pouch is large, adherent, and infected may be advisable, for in such circumstances duodenal obstruction may be severe [51] Surgical treatment is needed, however, *only in very rare conditions, for the orifice of the* pouch is, as a rule, large enough to allow of the easy escape of contents when an appropriate position is taken Removal of the diverticulum from the inner or posterior aspect of the second part of the duodenum may present the most formidable difficulties Case [11] records an example of duodenal diverticulitis with complication of the common bile-duct in which cholecystotomy gave relief

Diverticula of the Jejunum and Ileum

Diverticula of the small intestine of both jejunum and ileum are occasionally seen. Meckel's diverticulum is a well-known anomaly, and its surgical possibilities are quite understood Jejunal diverticula may, though rarely, cause distress The best example I have ever seen occurred in the practice of my colleague, Mr Braithwaite Enterectomy was necessary, and the very beautiful specimen is now in the Museum of the Royal College of Surgeons The diagnosis was made after a radiological examination by Dr L A Rowden The first diagnosis ever recorded stands to the credit of Dr Case Gordinier and Sampson [19] record an example of multiple diverticula of the jejunum , 13 pouches were found in a length of 40 cm All the pouches were on the mesenteric border One of them had become inflamed, causing partial occlusion of the lumen of the bowel Hansemann [34] *reported one case* in which over 400 diverticula were found, the majority were in the jejunum , and another case in which a diverticulum from the upper part of the jejunum contained pancreatic tissue at the fundus Boker,[7] in an inaugural dissertation, reported a remarkable instance of multiple diverticula , there were two in the duodenum, many in the small intestine, many in the colon, and one in the urinary bladder One of the jejunal diverticula had ulcerated and undergone subacute perforation A case occurring in an infant 5 weeks old is recorded by Cautley [12], a cyst which was formed by the pouch had two openings into the intestine , it was larger than the stomach and had caused obstruction Scot Skirving [53] has carefully discussed this condition, which is not, I believe, nearly so infrequent as we suppose, though it rarely causes symptoms The pouches may be numerous, are rarely larger than a walnut, are usually on the mesenteric side, and because of their large orifice do not, as a rule, retain food for long periods, and do not, therefore, often lead to serious complications.

Diverticula of the Large Intestine.

This condition is a common *one* At first recognised by the pathologists, it was hardly considered by the clinicians until the increasing frequency of abdominal operations and the aptitude of radiologists revealed the truth

The earliest description, perfect and almost complete in its accuracy, was given by Cruveilhier [16] In *recent* years attention was attracted to the subject by Graser,[21] by Beer,[3] and especially by Maxwell Telling,[57] and with *Gruner* [58] *The first case* recognised and recorded in this country occurred in a patient referred to me by Dr Helm,[26] of Carlisle The patient was operated upon for a duodenal ulcer causing hæmorrhage , attacks of intestinal obstruction had occurred, and the routine examination of the abdomen disclosed a "growth" in the sigmoid flexure which I excised Mr Harold Upcott examined the "growth" and proved its true nature This discovery led to our active interest in the subject and to the extended observations of Dr Maxwell Telling in the post-mortem room, and of my own in the operation theatre Cases soon occurred to show the frequency of the disease Patients were seen with "*left-sided* appendicitis" with "vesico-intestinal fistulæ," and with tumours in the left half of the colon believed to be malignant, all the cases proving to be examples of this disease An examination of several specimens in museums showed that "carcinoma of the colon" was often due to an inflammatory hyperplasia , and the truth of Harrison Cripps's [15] *observation that fistulæ between the colon and the* bladder were due more often to simple than to malignant disease *was confirmed Our knowledge* of the earliest phases of the disease, of its frequency and extent, of the method of formation of the pouches and of the slow rate of increase in many cases is due entirely to the radiologists, among whom that accomplished artist, Mr O A Marxer, deserves mention for his discovery of the "prediverticular stage"

Diverticula are found in all parts of the colon, most commonly in the appendix, least frequently *in the* rectum Spriggs and Marxer[54] found them 100 times in 1000 consecutive examinations They found only five cases in the appendix, where the disease occurs quite frequently in association with chronic appendicitis I have certainly seen it not less than 200 times. In *the* rectum it is a cause of multiple fistulæ more often than is supposed , the failure *of many* operations for this condition is *owing to a lack* of appreciation of this truth The cause of the condition is a yielding of the intestinal wall, assumed *to* be the result of long-continued increased pressure within the lumen of the intestine The gut yields at its weak places, at points where vessels pass through the muscular coats, or where appendices *epiploicæ* are attached The mucosa stretches the muscular coat, and finally perforates it as the diverticulum increases in *size* I am of the opinion that in some cases at least the disease may be congenital in origin For the smaller pouches may show all the coats of the intestine, in this sense being "true" , and the history of the case occasionally *dates back to the early years of life* There is certainly in some cases a muscular weakness of the intestinal wall, which *makes* the development *of* diverticula more easily possible The shapes *of* diverticula vary Often they have *the contour of* a flask with long, narrow neck and oval cavity. Into the cavity fæcal material enters through *the* tubular neck, and finds *difficulty* in escaping As it lodges there in slowly increasing amounts it enlarges its containing cavity, and at last *may set up inflammatory* changes

CONDITIONS DEVELOPING IN DIVERTICULA OF LARGE INTESTINE

The following conditions may then develop —

1 *Diverticulitis* —Attacks of acute and subacute inflammation due to infection of the diverticulum by its retained and septic contents

2 *Peridiverticulitis* —Inflammation round a number of diverticula results in a large indurated solid mass , the intestinal wall becomes greatly thickened and there is often a close mimicry of carcinoma

3 This inflammatory phlegmon may undergo cicatrisation and contraction, causing a *stenosis* , in consequence of this *obstruction* of the intestine, acute, or chronic, or acute supervening upon chronic, may occur

4 *Local peritonitis* around the diverticula, in consequence of their deeper penetration of the intestinal wall, with infection of the peritoneum clothing the outer surface of the gut This may result in *adhesions* between the involved intestine and any neighbouring viscus or the abdominal wall *Fistula* may form and lead *to the small intestine*, the bladder, or on to the anterior abdominal wall or ischiorectal fossa Vesico-intestinal fistulæ are more frequently *due to* diverticulitis than to any other cause

5 As the diverticula deepen, ulceration may occur at the base of them and in consequence a *perforation* may result In this way acute general peritonitis, subacute localised peritonitis, a localised abscess, or suppuration in a hernial sac may be caused

6 *Chronic mesenteritis* may be caused by the diverticula insinuating themselves *between* the leaves of the mesocolon, especially of the sigmoid flexure

7 *Carcinoma* of the colon or the rectum may *be a result* of the chronic irritation of the stagnant and putrid contents of the diverticula Judd and Pollock doubt whether the incidence of carcinoma is greater in the patient suffering from diverticulosis than in the normal individual. ,

A "prediverticular state" of the colon has been thus described by Spriggs and Marxer[55]

"The appearance (in the radiograph) is characterised by a ragged outline of the wall of the bowel which does not dilate even in the most favourable position. If one aspect only of the wall is involved the contraction is less This appearance is not the result of irritation from the small hernia but precedes their formation."

They believe that in this stage there is a weakening of the intestinal wall due to thinning of the muscular coat, which allows the penetration of the mucous membrane under pressure

Symptoms —Multiple diverticula may exist without causing any clinical manifestations Vague intestinal discomforts and some causes of "colitis" are explained by their presence Chronic constipation is their frequent, but certainly not invariable, antecedent Constipation may sometimes be the cause of spurious diarrhœa, the bowel, though discharging its contents freely and frequently, shows on X ray examination an inertness responsible for delay in the passage of the fæcal mass As the pathological changes advance the following clinical groups may be recognised ·—

1 *Inflammatory* —The patient suffers from recurring attacks of greater or less severity, in which localised pain, tenderness, rigidity, and swelling are present Temporary intestinal difficulty accompanied by vomiting may be observed The symptoms are so similar to those caused by inflammation of the appendix that "left-sided appendicitis" is spoken of in many instances A large phlegmon occupying the iliac fossa is not seldom found and in two cases of mine proved to be caused by diverticulitis associated with actinomycosis In other forms an acute general peritonitis is found, and at the operation a perforated diverticulum is disclosed A case of perforation of a cæcal diverticulum mimicking acute appendicitis is recorded by Pereira[44]

2 *Obstructive* —Chronic intestinal difficulty, with periodic attacks of exaggerated difficulty amounting to temporary obstruction, is not infrequent, in the severer cases a complete intestinal obstruction may be present The symptoms resemble those of carcinoma

3 *Fistulous* —The passage of fæcal matter and air by the urethra indicates that a communication exists between the intestine and the bladder The opening may be seen with a cystoscope The frequent cause is a diverticulitis of the sigmoid flexure Fistulæ may open on to the skin of the abdominal wall, or rarely on the buttocks and in the ischiorectal fossæ

4 *Pelvic* —An inflammatory mass is found in the pelvis, and in the female is attributed to disease of the uterine adnexa The symptoms are often very similar to those of salpingitis and pyosalpinx

The association of diverticula with infections elsewhere, especially in the teeth or in the facial sinuses, must be remembered *Bacillus coli* infection of the bladder or kidney is sometimes associated with this disease, but rather as an effect than as a cause

DIAGNOSIS AND TREATMENT

Increasing experience of this disease allows a diagnosis to be made with accuracy in the more pronounced types But all clinical evidence is subordinate to that offered by the radiologist In cases where a tumour is present, the duration of the disease, its wavering course, the liability to attacks of inflammatory disturbances alternating with intervals of freedom, the absence of blood in the stools, the presence of mucus in excess, will all suggest a simple rather than a malignant origin

In the great majority of cases *medical treatment* will keep the symptoms in check All possible sources of infection must be investigated A diet leaving little residue is the one generally advised, but I am not sure that a diet leaving a bulky residue is not better, provided that the bowels act once or twice daily Paraffin is given twice daily, at first in amounts as large as the patient can tolerate, and later in diminishing amounts A large soap-and-water enema slowly administered once every week or ten days may be given, especially in the earlier months of treatment, and a very large dose of bismuth may usefully be administered from time to time in the hope of subduing infection Operative treatment is directed only to the needs of the severe cases The extent of the disease in some cases makes removal prohibitive. I have performed colotomy in cases of severe obstruction, and after the lapse of one or two years have been able, after the disappearance of the tumour, to close the intestine The first case upon which I did this occurred in a patient now 86 years old Mayo Robson had performed colotomy for a large mass low down in the pelvic colon causing obstruction The lump gradually disappeared and the lumen of the bowel became patent There has been no intestinal difficulty since the closure and the patient has survived a prostatectomy subsequently performed The general surgical indications and methods need no special mention here

I was recently reading once again the life of William Hey, the founder of the Leeds Infirmary, and the first of the Hey dynasty, which served our hospital from 1767 to 1895 The account of his illness, death, and post-mortem examination leave me in no doubt that diverticulitis had led to a perforation of the large intestine

Few subjects in surgery are so littered with inaccurate references and incorrect names as this With the help of Mr Powell, of the Royal Society of Medicine, I have prepared the above list I am greatly indebted to Prof J Kay Jamieson for his dissections which made clear the point of origin of the lateral pharyngeal diverticulum

MULTIPLE DIVERTICULA OF THE COLON

By EDMUND I. SPRIGGS, M D, F R C P LOND.,
SENIOR PHYSICIAN,
AND
O A MARXER,
RADIOGRAPHER, RUTHIN CASTLE.

(WITH ILLUSTRATIVE PLATE)

Introduction.

IN the course of the observation and treatment of 208 cases of multiple diverticula of the large intestine it has been possible to study a great number of instantaneous photographs of the affected part of the bowel and, in some cases, to watch the progress of the disease over a series of years Many of these observations have been reported in former papers[1] It is proposed in this account to set forth the radiographic features of the stages of diverticulosis in somewhat more detail, and to summarise the clinical aspects, which have been more fully described elsewhere[2 3 4]

The definition we suggest for diverticulitis and the sections on ætiology, prognosis, and treatment, also some of the illustrations, are based upon the remarks made, and the slides shown, by one of us in opening the recent discussion on diverticulitis at the Royal Society of Medicine[4]

Multiple diverticula of the colon have been recognised for over a century by pathologists, but not till the last ten years, since the radiology of the bowel has grown more precise, has it become known how often they are present, and are the cause of disease A summary of the history of the subject is given in a former paper in the *Quarterly Journal of Medicine*[2] References will there be found to various papers up to 1924, including the monographs of Bensaude, Caine, and Hillemand (1913) and of Telling and Gruner (1917), who give large bibliographies Papers we have been able to consult which appeared from 1925 to 1927 are mentioned in the report on the above-mentioned discussion[4]

Statistics

Some stage of diverticulosis of the large intestine was found in 10 per cent[5] of 1000 consecutive patients admitted to this hospital in whom an X ray examination of the alimentary canal was made, two men being affected to one woman From this frequency it may be assumed that it would also be found in some of those complaining of symptoms not thought to concern the alimentary canal, and who were not examined with barium Further, since half the people with small diverticula of the colon suffer no inconvenience therefrom, they are probably present in a not inconsiderable proportion of the general population over 50 years of age

Diverticulosis is nearly always found in the latter half of life The average age of 1000 patients was 45, that of 100 diverticulous ones being 58 The condition has been described in children, but is rare; the youngest in our series was 25

The distribution of the diverticula in 166 consecutive cases was as follows —

Pelvic colon	120	Whole colon	24
Descending colon	79	Cæcum	8
Ascending colon	33	Appendix	6
Transverse colon	33	Rectum	4

The Stages of Diverticulosis

We have previously described the following stages in the development of multiple diverticula of the colon

(1) *The Prediverticular State* —This is illustrated by the full page photograph, Fig W, which shows a large piece of the descending colon at this stage The normal segmentation of the bowel is absent, being replaced by a ragged outline of little convex irregularities These are best seen quite close to the arrow leading from the word "colon," but are evident along the whole course This photograph (which we have published formerly but in a much smaller size) is a good one for showing what is meant by the prediverticular state, but it is seldom that so large an area of the bowel wall is involved The prediverticular state is often seen along one side of the bowel only, it may be seen in even part of one haustrum (Fig A), the rest of the haustra and the opposite aspects of the bowel wall showing healthy outlines In nearly all cases small diverticula can be seen in some part of the bowel at the same time as the prediverticular state, or if the case is observed again at intervals they will be found to develop at that area This stage precedes the formation of the pouches, and it is apparently associated with some weakening of the submucosa and of the muscular layers, it is while the prediverticular state is in evidence that the minute herniæ, which subsequently form diverticula, are pushed between muscle-fibres

(2) A stage of irritation is often seen to follow the prediverticular stage This is shown on the lower border to the right in Figs C and S Since the prediverticular state was first described, some writers have mistakenly regarded that appearance as what was meant The larger concertina-like appearance, however, is usually to be observed in a part of the bowel which has formerly been in the prediverticular state.

(3) *The Developed Diverticula* —These are of various sizes and shapes, some of them, even large ones, may contain all the coats, including muscle-fibres, as is shown by the fact that they can be observed to contract In a few instances even large pellets of fæces can be passed out of them from time to time if the necks are wide enough and not inflamed Indeed, these masses appearing in the fæces have sometimes been called soft gall-stones Others of the developed diverticula show very little muscle-fibre The shadow obtained with barium meal or enema differs according to the width of the neck of the pouch If the neck is wide enough the barium may enter the whole of the diverticulum and fill it, as shown in some of those in Fig V (illustrative plate) If the neck is narrower the barium does not displace the former contents, but fills only the lower part of the pouch lying next to the neck, giving a crescentic shadow such as is also seen in Fig V These crescentic shadows are characteristic. When the neck of the diverticulum is very narrow, material cannot get out and hardens *in situ*, forming what is called a stercolith A stercolith of long standing may cause a shadow which can be recognised without a barium meal

(4) *Diverticulitis* —At this stage inflammatory processes arise about the necks of pouches, especially of those containing stercoliths, and spread to the wall of the bowel, giving rise to a local colitis or pericolitis.

Method

The opaque meal found to give clear pictures of detail consists of 120 g of barium sulphate suspended in 500 c cm of Horlick's malted milk or buttermilk This appears to fill every crevice in the colon, and has often shown diverticula that had remained undetected with other suspensions The enema consists of 400–450 g of barium sulphate made up to two pints with buttermilk, warmed to body temperature The meal enables certain points to be observed, the enema others For example, the former, which mixes with the secretions and is more like the natural ingesta, shows the distribution of the food and its rate of passage along the gut, especially before and after defæcation, any constrictions or spasm and the position of the ingesta at times of pain or discomfort; it may also fill stercolith-bearing diverticula better than the enema, whilst with the latter it can be seen how far the different parts distend normally or are constricted In over 200 cases observed with both meal and enema, in only two did the enema fail to show diverticula

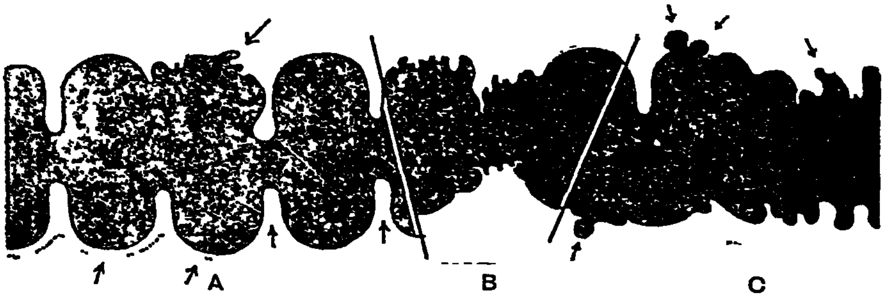
[4] Proc Roy Soc Med, 1927 xx, 665
[5] Since our former papers were published a certain number of patients has been admitted in whom the disease was already suspected or diagnosed, increasing the incidence by selection But that was not the case during the time from which the above quoted series was taken

Both screening and radiography must be employed, the one guiding the other, all parts of the bowel being brought into view at some time with either meal or enema If this cannot be done the examination is so far incomplete This applies especially to cases in which diverticulitis is suspected The mere demonstration of residues showing the presence of diverticula must not be the height of the radiographer's ambition All possible data must be gathered to ensure a reliable judgment as to diagnosis, prognosis, and treatment

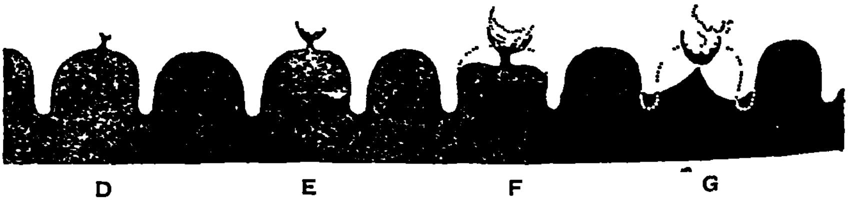


A' = Normal haustra below and small patches of prediverticular state above
B = Areas of prediverticular state involving circumference of bowel and causing apparent ring constriction
C] = The same piece of bowel (as B) after treatment No constriction Irregularities, the aftermath of prediverticular state, also small pouches in formation

In all these figures (A to U) the text should be consulted for the full description

It is reported that diverticulitis may be present without radiographic demonstration of diverticula This is not yet within our experience, but is, of course, possible, though unlikely if both meal and enema are used In any case a localised diverticulitis, even after all pouches have been deformed beyond recognition, has the characteristic appearances described below

The normal bowel wall is generally engaged in a slow contraction or dilatation This can be demonstrated by taking serial films at one second's interval, with an instrument like a slow cinema camera, designed by one of us When such a film is placed accurately upon another one the extent of the movement can be seen A rigid piece of bowel wall, the seat of diverticulitis, shows no movement and can by this means be recognised



D = Small narrow necked diverticulum retaining fæcal material
E = The same diverticulum four years later
F = Large stercolith bearing diverticulum The dotted line shows the position at phase 1 of a serial film, the continuous outline at phase 2—i e, one second later—demonstrating the movement of a haustrum
G = Also from serial films showing the maximum contraction of this haustrum

When a lesion lies within reach of the sigmoidoscope that instrument should be employed With suitable preparation and care its use should be painless, and no general anæsthetic needed

Development of Diverticula

The radiographic appearance of scalloping in the normal colon is known as haustration, and any single scallop as a haustrum The lower silhouette of Fig A shows such a normal outline of a barium-filled bowel, the dotted line represents the peritoneal surface The arrows on the left of the letter "A" indicate the haustra

The deep indentations which almost bisect the lumen of the colon determ [illegible] segmentation (see the two arrows on the ri [illegible] ter "A") They are regular and symme [illegible] e bowel be bent at an angle The co [illegible] res cause the segmentatio [illegible] of the bowel wall The [illegible] o

clefts or divisions between the haustra, but does not enter them

A simple mucosal lesion of the bowel does not always give radiological signs of its presence, but when the submucous and muscular layers are involved the normal segmentation of the colon is altered and the change is visible

The temporary absence of segmentation during mass movements is called inhibition

In the following more detailed study of the development of diverticula each figure is, unless otherwise stated, an exact tracing from a photograph, and not a diagram The black area is the barium filled lumen of the bowel

Prediverticular State—In the early prediverticular state, if only small patches are affected, the shape of the haustrum may be almost unaltered, provided the patch is not near an interhaustral cleft If it is, a curtailment in depth and a displacement of the cleft result

Fig A is a tracing from a stretch of sigmoid showing such a spread-out haustrum The small indentations denote the prediverticular state The arrow above points to a minute hernia or diverticulum Owing to the diverticulosis the upper two haustra have come together, the cleft between them having almost disappeared This shows how the irregular segmentation arises in a diverticulous bowel On the opposite aspect of the bowel, the lower in this photograph, both haustra and clefts are regular If the prediverticular state involves large areas, haustration may become unrecognisable, and segmentation disappear If only one side of the bowel is involved there will be interference with the diameter of the lumen, when the whole circumference of the bowel is implicated, narrowing is considerable, and a ring constriction may be simulated

Fig B shows such a piece of bowel Part of the upper border was prediverticular, and another short stretch is involved in its whole circumference Note the consequent encroachment on the lumen as compared with the lumen in Fig A

Fig C shows the same stretch of bowel after treatment There is now no constriction Small pouches are visible on both borders, shown by arrows

In the prediverticular state the circular muscle fibres are contracted, as is shown by the narrow lumen, and the mucosa is thrown into narrow folds It may be presumed that the longitudinal fibres are also involved After the passing off of the prediverticular state the haustra and the clefts between them tend to lose their symmetry The appearance suggests that muscle-fibres are damaged, being thinned in places, with corresponding bunching in others, as when an elastic band is cut or weakened in one place Judging by repeated observations at intervals of a year or more, any given haustrum tends to remain distorted in the same manner, and thus haustral asymmetry may persist in an otherwise flexible diverticulous bowel.

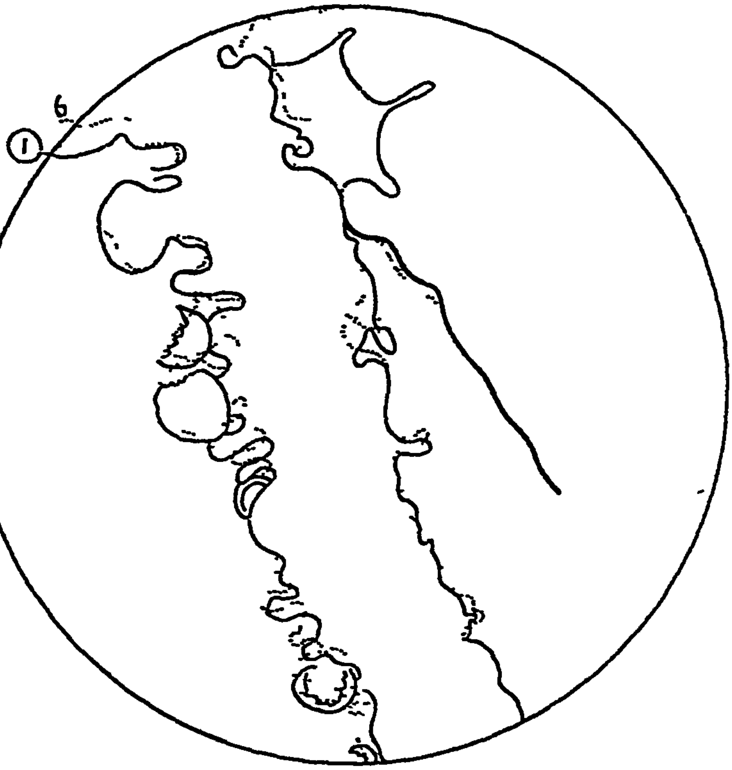
This is the stage 2 mentioned above. See the irregular nondescript contractions deforming the lower border of the bowel in C, the aftermath of the prediverticular state. This appearance occurs without excess of fat or evidence of any thickening of the wall.

Formation of Pouches.—When the small hernia forms, local conditions determine the size and position of the orifice, and upon these depend the type of pouch which will be developed.

In Carman and Miller's book on the "Roentgen Diagnosis of Diseases of the Alimentary Canal" (1917, p 471) is an excellent photograph of a microscopical section, showing a pouch of mucous membrane penetrating the muscular layer.

We have pointed out in former publications that the rate of emptying of a pouch depends on the size of its neck. This consideration, which is obvious enough, grows in importance with further study of small diverticula. The pouch which is likely in the future to set up diverticulitis is the one which cannot easily discharge its contents, and which barium enters in part only, giving a crescentic shadow. The content of such a pouch is liable to become inspissated and form a stercolith. We find that some pouches show these characteristics at a very early stage, for we see often minute herniæ with the appearance of stercolith-bearing diverticula.

FIG. H.



H = Tracing of two instantaneous photographs from the descending colon shown in Fig V, being phases 1 and 6 of a serial film—that is at about six seconds' interval—superimposed. Phase 1 is the continuous and phase 6 the dotted line. (See description of Fig V.)

Fig D shows such a diverticulum at an early stage. The bowel wall from which it arises is soft and flexible. The small pouch itself is spherical, but owing to its narrow neck it retained inopaque material when the food residues left that part of the gut, and there was no room for the opaque barium mixture except at its basal part.

Fig E is from the same case four years later. The haustrum is unaltered, though the pouch is much bigger. As before, the barium has crept round the fæcal content near the neck.

Fig F shows two phases of a serial film. There is a pouch with a stercolith. The dotted line shows the position in phase 1, and the continuous outline that in phase 2. There is a moderate degree of contraction of the dome of the haustrum.

Fig G, a later phase, shows the maximum contraction. The neck of the diverticulum is no longer showing, which means that its mucosal surfaces were apposed.

Fig H shows tracings of two instantaneous photographs at about six seconds' interval—i e , phases 1 and 6 of a serial film, from the descending colon of Fig V, superimposed, phase 1 being the continuous, and phase 6 the dotted line. The bowel wall is seen to be mobile, with its diverticula. The large diverticulum at the top on the left is capable of contraction. The stercolith-bearing one below it keeps its shape, but its position has changed with the movement of the part of the bowel from which it arises.

The Onset of Inflammation about a Diverticulum.—Fig. I shows again a pouch containing a stercolith. The block is, as before, the tracing of an actual film. The dotted line represents schematically the peritoneum. This is taut over the stercolith where the other coats of the diverticulum will also be thinnest. This is why such pouches are stiff and more spherical, whilst those with flexible muscular walls become somewhat pear-shaped during contraction.

When inflammation sets in there is a limitation of the flexibility of the bowel wall. The study of serial films at intervals shows that rigidity—i e , inflammatory change—begins at the necks of diverticula and particularly of those which carry stercoliths. Tension or friction in the narrow neck suggests itself as a cause, though perhaps stagnation beneath a stercolith is an equally harmful factor. Dr. A P. Cawadias[6] has described the microscopical appearances in diverticula which emit fæcal material with difficulty, the round-celled infiltration extending towards the serous envelope.

The earliest radiological sign is an encroachment on the haustrum as shown by a widening of the re-entering angle between the diverticulum and the bowel. This cup-shaped widened angle is shown by the arrows in Fig J. The encroachment is seen most plainly during inhibition. It may be symmetrical or one-sided; in the latter case there will be a tilting of the diverticulum. In other words, two deep indurations, which have the appearance of invagination, are seen during stages of relaxation.

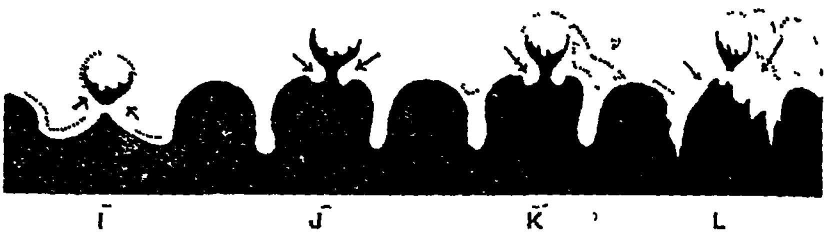
Fig K is a tracing from another film. The arrow shows such early inflammatory changes. Note the apparent sinking into the haustrum of the diverticulum. The peritoneal surface is added schematically, the shaded area representing fat.

In Fig L the inflammatory thickening (often called hypertrophy) is more advanced and is asymmetric. The lumen of the neck does not show; it is squeezed and contains no barium.

---

[6] Proc Roy. Soc Med , loc cit , p 691

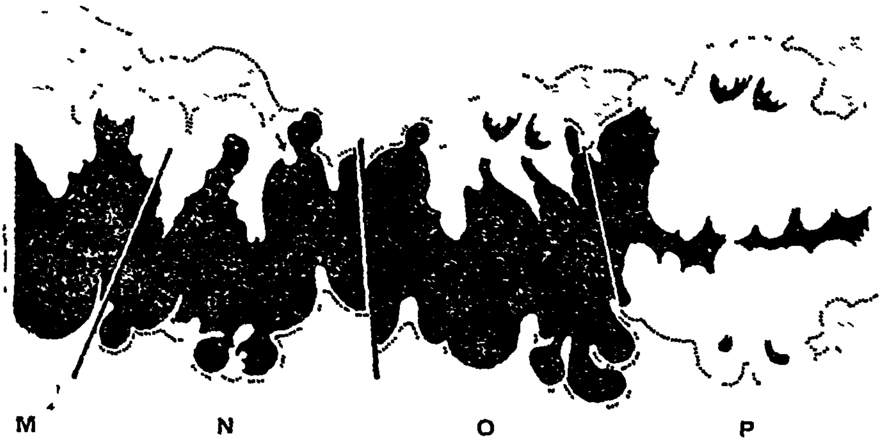
The inflammatory exudation and resulting fibrosis may affect certain wide-mouthed diverticula in quite another way, opening their orifices until nothing is left of the pouch but a stiff V-shaped irregularity with the open part facing the lumen The small projections from the black shadow on the upper border in Figs M and N show the remains of such pouches



I = A stercolith bearing diverticulum during maximum contraction of its haustrum The peritoneum is shown diagrammatically
J = Widening of the re entering angle at the neck of a diverticulum, the earliest radiological sign of inflammatory thickening of the bowel wall
K = Early inflammatory thickening showing the peritoneal surface schematically
L = More advanced thickening Note distance of lumen from peritoneal surface Cf I

On the lower border in Fig N two diverticula show evidence of thickening and rigidity of the bowel wall, but it is possible that they have been reached by extension of the process from the opposite side, just as the otherwise natural haustrum at the right on the upper border shows evidence of encroachment (see arrow) As the fibrous thickening increases at the expense of the haustrum, the more the stercoliths become separated from the lumen, as in Fig O, which shows 4 cm of bowel much involved on one side by inflammatory changes The dark isolated crescentic areas represent barium which entered by a narrow channel not visible in the film, and lies beneath stercoliths The diverticular necks appear to be, and no doubt almost are, obliterated The opposite, lower, aspect shows two large flexible diverticula, the haustra from which they arise, as well as the adjacent haustra, were over-active

Fig P is from the same piece of bowel as O but four years later. It shows how far the stercoliths have become separated from the exceedingly narrow lumen. The affected area is remarkably localised, for immediately below it (to the left) the lumen widens abruptly to its natural diameter This point was about 28 cm from the internal anal sphincter



M = Great thickening of bowel wall Diverticular necks opened up
N = Evidence of spreading of inflammatory changes to opposite lower wall
O = Isolation of diverticula from the lumen of bowel
P = The same four years later showing advanced obliterative stage

The characteristic radiological sign of diverticulitis, as mentioned below, is rigidity of the deformed bowel wall (Fig Y on illustrative plate and Fig. Z)

Inflamed mucosal folds give confusing appearances in diverticulitic films Serial photography is often the only means by which they can be differentiated from the fibrous thickening of the outer layers of the gut These folds are, of course, transparent to X rays and form the apparent clefts between the opaque barium-filled haustra In Fig Q mucosal folds (see arrows) have swollen into massive jagged nodes The peripheral inflammatory thickening was slight; there was enough to give some small diverticula an invaginated appearance, but not enough to prevent the bowel wall on which they lay from registering some movement in serial films To the right of the middle of Q, however, the palisade appearance is significant of massive inflammatory change This patient was operated upon and these conclusions confirmed. The figure is typical of the radiological appearance which would be given by many specimens of diverticulitic bowel such as are removed occasionally at operation, or, more often, post mortem

Swollen folds of mucous membrane are also the cause of the bulky invaginations in the shadow on the lower aspect of Fig. R, shown by arrows The rifts in the upper border of the shadow have the same cause It could be seen in serial films that when the haustra contracted so that the lumen was almost a thread, yet these did not recede or alter in size The bowel passes on the left into almost normal segmentation In this case areas of the prediverticular state and some minute diverticula were found close to the inflamed area

Association of Early Diverticulosis with Diverticulitis—We have several times observed that early disease—i e, either the prediverticular state or very small diverticula—is found close to an area of old-standing diverticulitis with stercoliths, all three stages together, and that in cases which have suddenly flared up, threatening obstruction It would be expected that the younger areas of disease had arisen from the older But early diverticulosis occurs in patches, and in two of our cases one of these separate areas appeared to be creeping towards the hypertrophic area rather than arising therefrom However this may be, it appears as if the encroachment of the new upon old standing disease had aggravated the chronic inflammation

Fig S is from a radiograph of a piece of bowel which is the seat of early and late stages of the disease. The arrows point to minute diverticula in process of formation in an area of the prediverticular state On the upper border are stercoliths and established rigid diverticulitic fibrosis

Fig T is from a patient who was admitted after an attack of subacute obstruction. We could not find evidence of inflammatory thickening though numerous large diverticula were present and some small ones Seven years later he had a recurrence of subacute symptoms and was readmitted. The same piece of bowel now gave Fig U. Small areas of the prediverticular state were seen and some minute pouches No evidence of gross thickening could be found in spite of careful search As there is no evidence of inflamed mucosal folds, although the last attack was recent, it appears probable that the threatened obstruction was due to severe spasm. The discomfort or pain corresponded on each occasion with the formation of new diverticula (See also Fig X on illustrative plate)

Ætiology

The ætiology of the disease is not yet understood In the first stage (the prediverticular state) there is irritation of the bowel wall with tenderness in that area on the X ray table and in some cases, in which a large part of the bowel is involved, pain is complained of clinically, though generally this stage is passed unnoticed by the patient. We have brought forward evidence[7] to show the frequent association of early diverticulosis with septic foci in other parts of the body, particularly the teeth, and with early arthritis of the spine—i.e, spondylitis This evidence leads to the view that the change is an inflammatory one in the first instance, probably bacterial, and not degenerative or passive That the small herniæ are prone to occur where the blood-vessels penetrate the bowel wall has been taken as evidence that they are passive extrusions from the beginning The lymphatics also penetrate with the blood-vessels, and it is possible that any inflammatory process, which would affect them more than the blood-vessels, would lead to weakness in their neighbourhood

How much constipation plays a part is not known The subjects are frequently constipated, but apparently not more so than other patients It is delay in the pouch, rather than in the bowel, which is harmful.

Flatulent distension of the bowel would be expected to aid in the formation of pouches and to cause enlargement of those already formed whose lumen is communicating with the bowel. The most serious result of diverticulosis, however—namely, the development of diverticulitis—arises from diverticula which have been almost completely blocked and would be least subject to changes of pressure from the interior of the bowel. It has been suggested that excess of fat plays an important part in the early stage of diverticulosis. The statistics of our cases, however, show that the diverticulous are not heavier than other patients of the same age and sex. In later stages, when diverticulitis threatens, fatty tissue around the bowel is probably less able to resist a spreading infection than the more vascular non-fatty peritoneum.

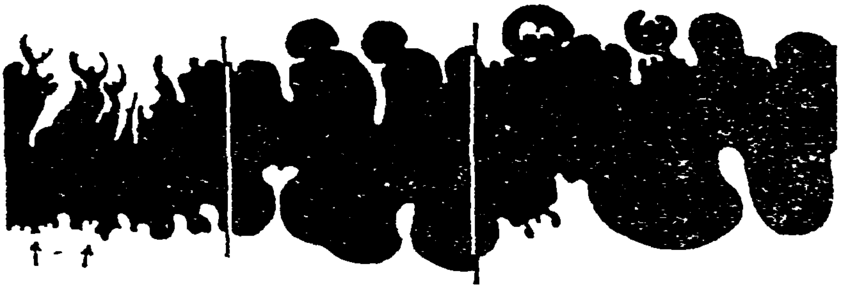
We have not observed any special association between spasm of the bowel and diverticulosis

Symptoms

As a rule, in the *prediverticular state*, no symptoms are recognised, though with increasing experience this rule is found to have exceptions especially if large areas are involved The area of the bowel affected, as observed with the X rays, is often in a more irritable condition than when diverticula are established. and is sometimes tender to palpation on the X ray table. In one case pain had been complained of in the lower and left parts of the abdomen for some weeks A great part of the descending and pelvic colon was found to be tender and in the prediverticular state and the symptoms yielded to treatment In another in which the colon was strewn with patches of the prediverticular state, pain was complained of as the barium entered the affected part of the bowel. In another in which most of the descending and pelvic colon was in the prediverticular state, these parts of the gut were tender and rigid, and there was aching over the sacrum after evacuation

Q = Shows the picture given by inflamed mucosal folds, also some small new diverticula superimposed on an old area of diverticulitis
R = Swollen folds of mucous membrane shown by arrows, also acute prediverticular stage supervening on chronic diverticulitis

The stage of *established diverticula*, short of diverticulitis, may be quiescent for years. In our series half the subjects complained of no symptoms referable to the pouches In the others there was some clinical evidence of irritation of the bowel, or, less often. of the peritoneum or bladder. The symptoms mentioned were, in order of frequency, flatulence, pain. distension or indigestion, generally below the navel and most often on the left side, pain or discomfort before or after defæcation. diarrhœa, or alternating constipation and diarrhœa. A few have irregularity of, or discomfort with micturition.



S = Acute early diverticulosis (lower border) supervening on an area of old diverticulitis (upper border)
T = Diverticulous bowel.
U = The same piece of bowel seven years later showing new disease supervening on the old area of diverticulosis

The symptoms of *rupture of a pouch* into the peritoneum are those of an acute local or general peritonitis This accident is fortunately uncommon The symptoms of diverticulitis are described in the following section

Definition of Diverticulitis.

Diverticulitis is the final stage of diverticulosis, at which the small pouches, as already described, become involved and destroyed in the chronic inflammatory process which in the first instance arose in themselves Sir Berkeley Moynihan drew attention to the clinical importance of this disease in 1907. Dr. Telling's papers (1908 and 1917), from the same school are an exhaustive pathological and clinical study of the condition.

Some seven years ago one of us proposed the term "diverticulosis" for the earlier stages of the disease, which are often free from symptoms and always, with the exception of the occasional rupture of a

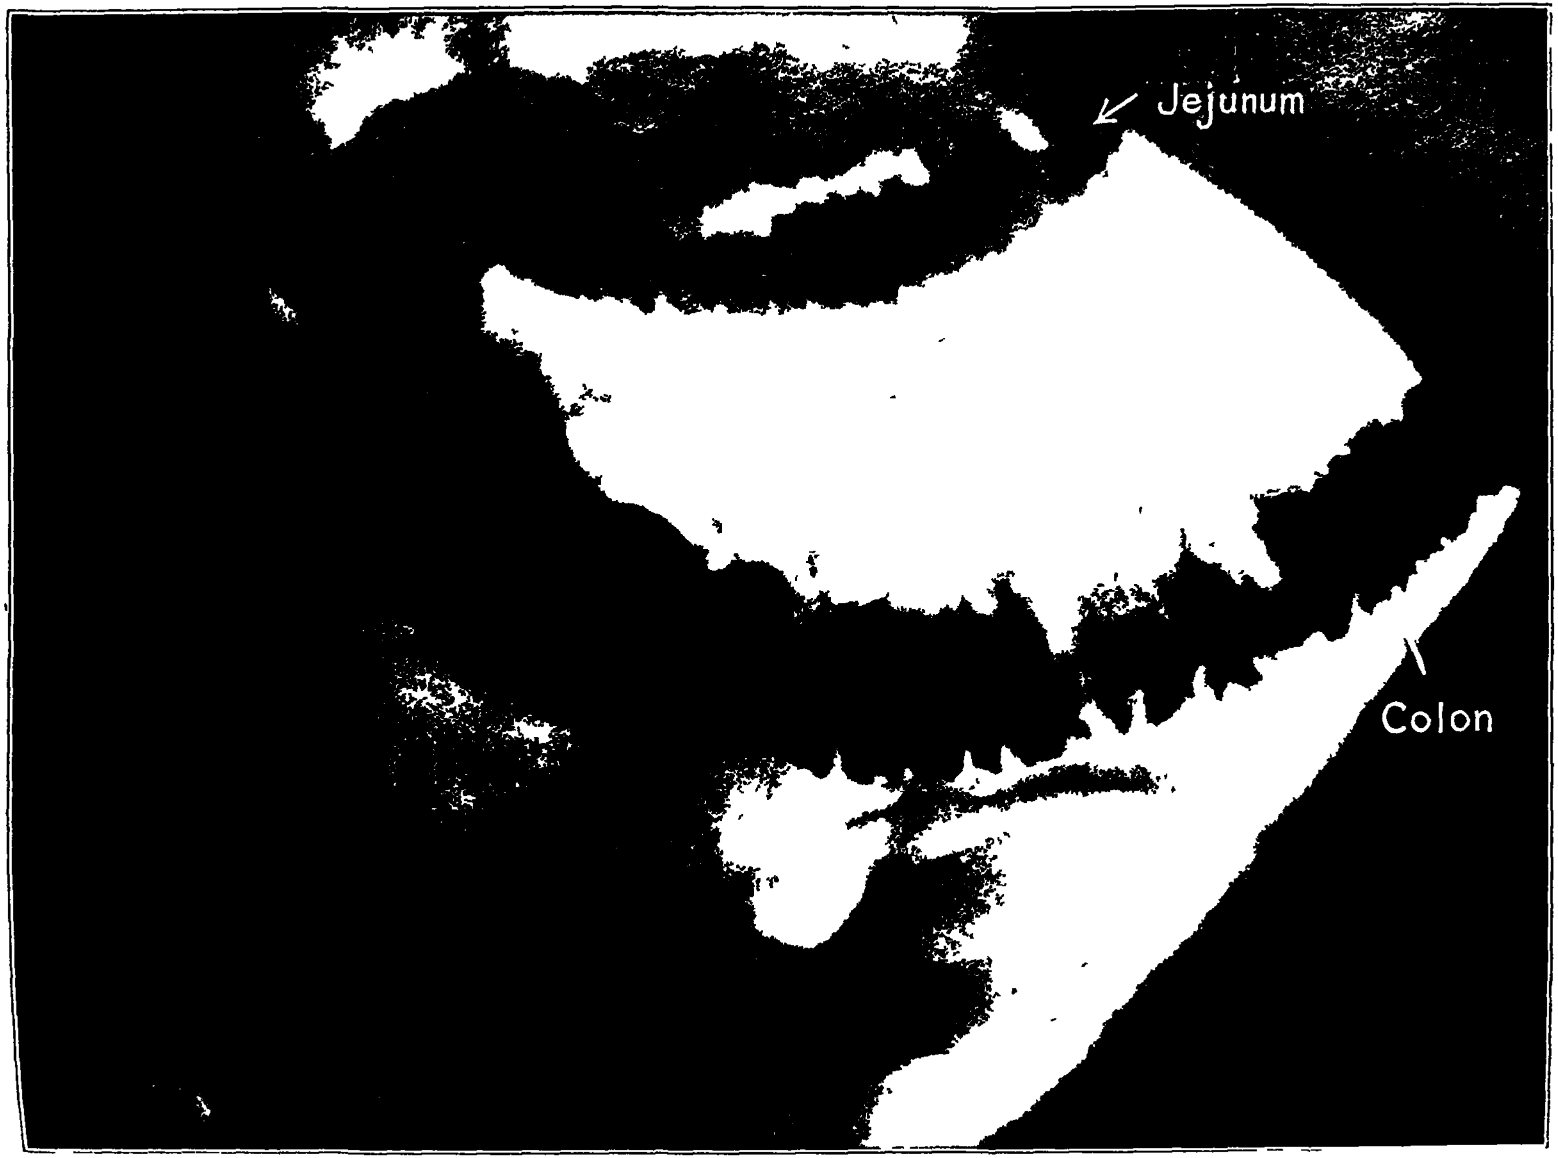
MULTIPLE DIVERTICULA
OF THE COLON

FIG W.



Oblique view of a prediverticular state of the pelvic colon Note the shallow convex impressions on both outlines from the pelvic brim upwards These are not to be confused with the deep serrations caused by spasm in other phases of the disease Note also how the colon simulates the appearance of the normal small bowel No diverticula yet present in the portion of bowel on the right small early ones can be seen to the left near the pelvic brim single pocket, free from severe symptoms We did not know until this year that de Quervain,[8] the Swiss surgeon, had made the same proposal in 1914 in a paper not then accessible to us Any degree of irritation and inflammation arising in a pouch may logically be described as diverticulitis But in practice a distinctive term is needed for the later stage which constitutes a definite and serious disease from which most of the subjects of diverticulosis never suffer

The *clinical features of diverticulitis* are those of a low form of inflammation in the large bowel usually in the left lower abdomen, spreading to neighbouring structures

Abdominal discomfort less often pain not as a rule related to food, is situated about or below the navel, but especially in the left iliac fossa. It may be intermittent, with intervals of several weeks or longer The pain may be severe and is often accompanied by a general feeling of ill-health: it may take the form of a dragging sensation and backache General flatulence and a feeling of distension are usually mentioned and may be the only symptoms; an advanced state of diverticulitis may, indeed be present with but little complaint, in several there was no actual pain.

Constipation irregularity of the bowels, diarrhœa, or a sense of incomplete evacuation is frequent The increasing constriction leads slowly, usually very slowly, to obstruction

In cases of implication of the bladder there may be *frequent micturition*, sometimes painful after the bowels are opened; or a painless micturition may be followed by pain in the tumour.

A sausage-shaped *tumour* sometimes tender but not always, can be felt in the left iliac fossa, except in the very obese It may become acutely inflamed with pyrexia and vomiting Diverticulitis sometimes occurs at other parts of the colon

Hæmorrhage, per rectum excluding that from piles, we have seen three times, but it is not usual the inflammatory lesion lying as a rule without the mucous membrane

The *radiological features* of diverticulitis are definite With a barium meal or enema, typical rounded, oval, or crescentic shadows of the barium in the diverticula will usually, though not always, be recognised in the neighbourhood They are not, however, the characteristic features; these, which we have already described above in detail, are the spike, or palisade-like projections of barium shadows from the lumen of the bowel, the wall of which is thickened (from inflammatory exudation) and fixed. Serial films, when superimposed, show no variation in the outline of the shadows, although there may be vigorous and irritable contractions of the bowel wall above and below, or even in the same part of the gut opposite to the rigid area (See Fig Y on illustrative plate and Fig Z)

The *pathological features* are those of a chronic inflammation of the pelvic colon arising at first from one or more diverticula, but now involving all the coats of the gut including, sooner or later, the peritoneal coat and spreading to surrounding parts, especially to the bladder in men, but also, at times, to the uterus ovary, small intestine, or abdominal wall An excellent description of the morbid histology will be found in Telling and Gruner's paper Leucocytosis is frequent In late stages small, or sometimes larger, abscesses form in the inflamed or septic area Metastatic abscesses are unusual, but have been recorded

We put forward[9] the suggestion that the term diverticulitis should be reserved for those cases in which there is the combination of these three pictures—clinical, radiological, and pathological.

Diagnosis

(*a*) *Clinical* —Vague persistent or recurrent abdominal symptoms in a middle-aged, well-nourished person, which are not accompanied by physical signs and do not yield to simple medicines such as carminatives or mild purges give rise to the suspicion of *diverticulosis* The diagnosis can only be established by an X ray examination of the bowel The recognition of diverticula is not enough, as they may coexist with other lesions It must be shown, so far as possible, that diverticulosis is the only diseased state which is likely to be causing the symptoms

The diagnosis of *diverticulitis* is less difficult when a tender sausage-shaped swelling can be felt in the left iliac fossa especially if there is pain during or after evacuation, but must be established by radiography. The long history, the well-being of the patient in the intervals of symptoms the absence as a rule of bleeding from the bowel or of much mucus are against malignant disease. The possibility of a left-sided appendicitis will be remembered, also of actinomycosis and pyosalpinx When suppuration has occurred a differential diagnosis becomes of less importance for the abscess must in any case be drained

(*b*) As regards the *radiological diagnosis*, the prediverticular state must be distinguished from colitis. The latter causes inhibition or spasm without affecting the symmetry of the segments; the outline is smooth or any irregularities are nondescript In the prediverticular state the symmetry is disturbed as above described, and if there is inhibition the irregularities show small twin convex impressions Pericolic affections, such as tuberculosis, or inflammation where a jejunocolic fistula is threatening, may be indistinguishable in appearance from the prediverticular state

The *established diverticula* are generally unmistakable In a highly-placed mid-transverse colon where good oblique views are difficult to get there may be confusion with haustral residues; these, however, will become less opaque as the bowel clears In other parts it should be possible to get a view at the right angle to bring the suspected pouch into profile A film should be taken after the lumen of the bowel is free from barium

In *diverticulitis* the above-described rigidity and deformities of the bowel (from J to S) with a narrowed lumen are characteristic Diverticula sometimes new ones, will generally be seen near by If growth occurs at a diverticulous area, the concave (fingerprint) encroachments on the lumen may be recognised

Prognosis.

Were the outlook judged by the end-results of diverticulitis from the operating and post-mortem rooms of large hospitals[10] it would be grave indeed A more hopeless condition to deal with than a suppurating sigmoid, involving and infecting surrounding parts, can hardly be thought of apart from active malignant disease But as we have shown above, diverticulosis may be quiescent over long periods of time The cause of diverticulitis is inflammation in a pouch What chance is there of preventing or allaying this? There is none unless the existence of the pouch is known If every case of vague persistent or recurrent abdominal discomfort were investigated not only would diverticulosis but many other conditions be discovered at a stage when the most help can be given The doctor's difficulty is that patients want the aches and pains to be cured by a bottle of medicine or a pill; and when such simple measures do not suffice the patient still would like to "wait and see how he gets on" The loss of health and efficiency from such delays is incalculable

When a case of diverticulosis or early diverticulitis is recognised the prognosis is good, as a rule, for reasonable health and for life The disease responds well to treatment The graver complications occur chiefly in unrecognised or neglected cases Both before and after inflammatory changes the physician and

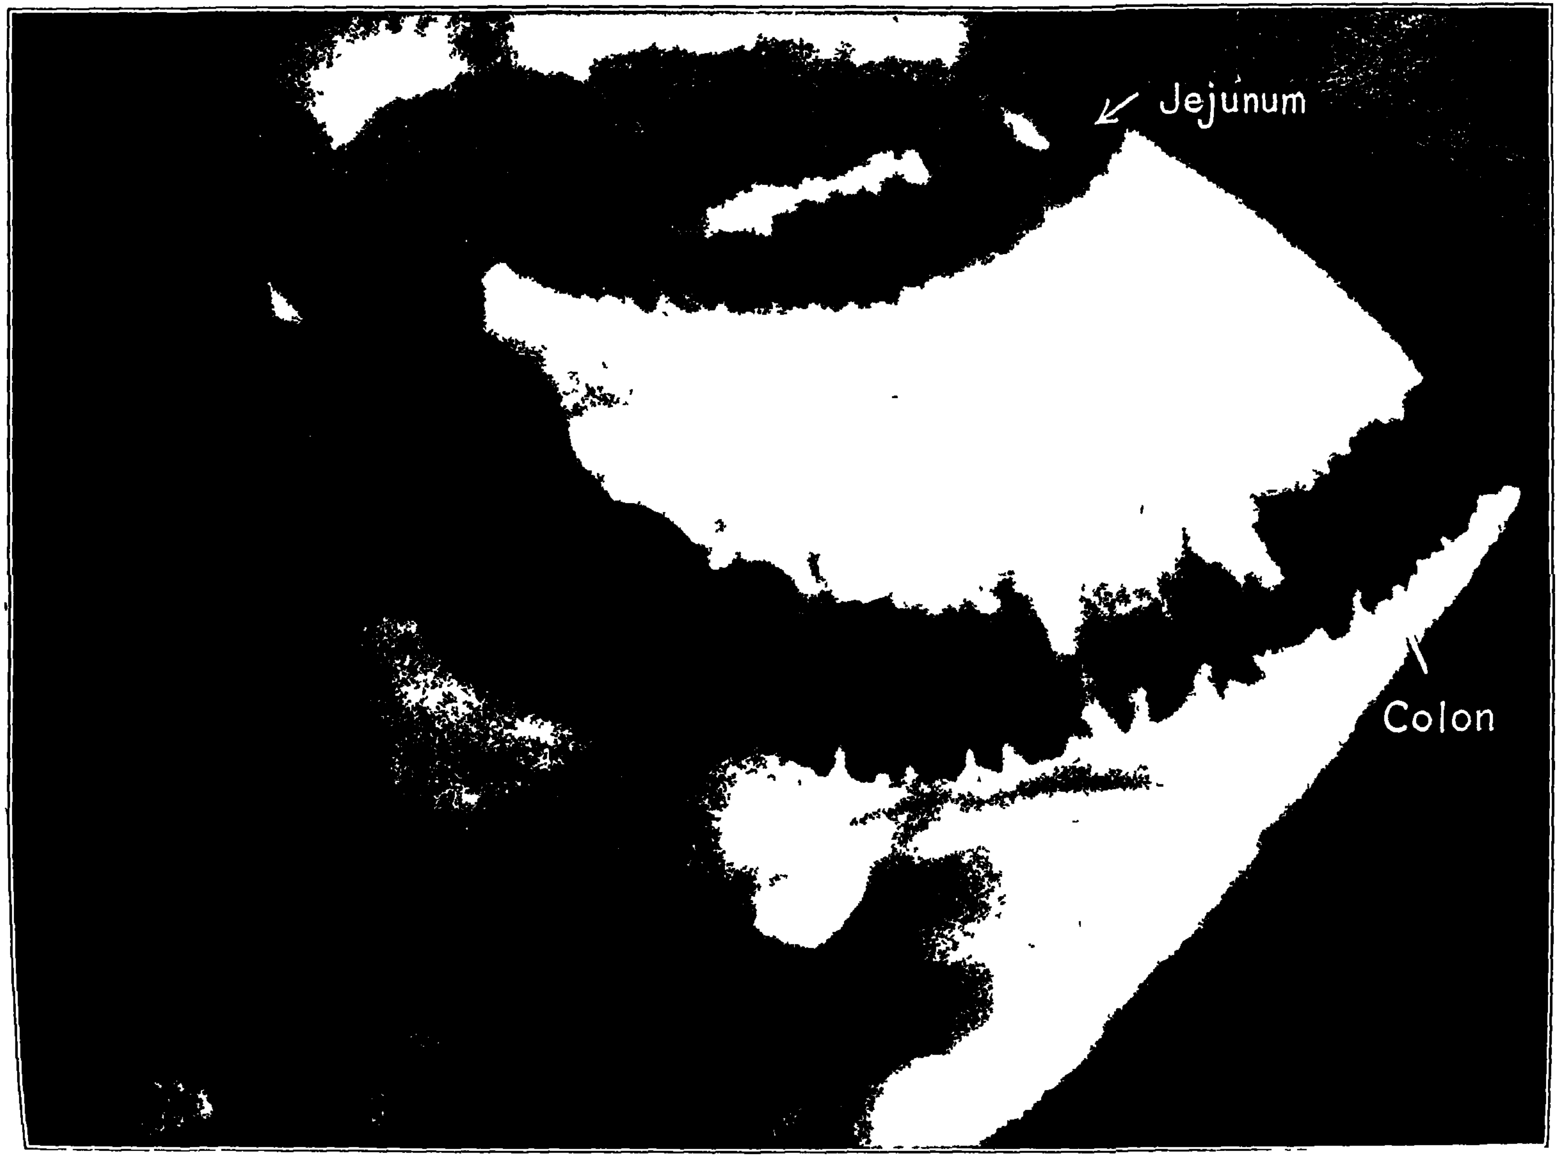
FIG W.



Oblique view of a prediverticular state of the pelvic colon Note the shallow convex impressions on both outlines from the pelvic brim upwards These are not to be confused with the deep serrations caused by spasm in other phases of the disease Note also how the colon simulates the appearance of the normal small bowel No diverticula yet present in the region of bowel on the right; small early ones can be seen to the left near the pelvic brim single pocket, free from severe symptoms. We did not know until this year that de Quervain,[8] the Swiss surgeon, had made the same proposal in 1914 in a paper not then accessible to us. Any degree of irritation and inflammation arising in a pouch may logically be described as diverticulitis. But in practice a distinctive term is needed for the later stage, which constitutes a definite and serious disease from which most of the subjects of diverticulosis never suffer.

The *clinical features of diverticulitis* are those of a low form of inflammation in the large bowel, usually in the left lower abdomen, spreading to neighbouring structures.

Abdominal discomfort, less often pain, not as a rule related to food, is situated about or below the navel, but especially in the left iliac fossa. It may be intermittent, with intervals of several weeks or longer. The pain may be severe, and is often accompanied by a general feeling of ill-health; it may take the form of a dragging sensation and backache. General flatulence and a feeling of distension are usually mentioned and may be the only symptoms; an advanced state of diverticulitis may, indeed, be present with but little complaint; in several there was no actual pain.

Constipation, irregularity of the bowels, diarrhœa, or a sense of incomplete evacuation is frequent. The increasing constriction leads slowly, usually very slowly, to obstruction.

In cases of implication of the bladder there may be *frequent micturition*, sometimes painful, after the bowels are opened; or a painless micturition may be followed by pain in the tumour.

A sausage-shaped *tumour*, sometimes tender, but not always, can be felt in the left iliac fossa, except in the very obese. It may become acutely inflamed, with pyrexia and vomiting. Diverticulitis sometimes occurs at other parts of the colon.

Hæmorrhage, per rectum, excluding that from piles, we have seen three times, but it is not usual, the inflammatory lesion lying as a rule without the mucous membrane.

The *radiological features* of diverticulitis are definite. With a barium meal or enema, typical rounded, oval, or crescentic shadows of the barium in the diverticula will usually, though not always, be recognised in the neighbourhood. They are not, however, the characteristic features; these, which we have already described above in detail, are the spike, or palisade-like projections of barium shadows from the lumen of the bowel, the wall of which is thickened (from inflammatory exudation) and fixed. Serial films, when superimposed, show no variation in the outline of the shadows, although there may be vigorous and irritable contractions of the bowel wall above and below, or even in the same part of the gut opposite to the rigid area. (See Fig. Y on illustrative plate and Fig. Z.)

The *pathological features* are those of a chronic inflammation of the pelvic colon, arising at first from one or more diverticula, but now involving all the coats of the gut, including, sooner or later, the peritoneal coat, and spreading to surrounding parts, *especially to the bladder* in men, but also, at times, to the uterus, ovary, small intestine, or abdominal wall. An excellent description of the morbid histology will be found in Telling and Gruner's paper. Leucocytosis is frequent. In late stages small, or sometimes larger, abscesses form in the inflamed or septic area. *Metastatic abscesses* are unusual, but have been recorded.

We put forward[9] the suggestion that the term diverticulitis should be reserved for those cases in which there is the combination of these three pictures—clinical, radiological, and pathological.

Diagnosis.

(*a*) *Clinical.*—Vague persistent or recurrent abdominal symptoms in a middle-aged, well-nourished person, which are not accompanied by physical signs and do not yield to simple medicines such as carminatives or mild purges give rise to the suspicion of *diverticulosis*. The diagnosis can only be established by an X ray examination of the bowel. The recognition of diverticula is not enough, as they may coexist with other lesions. It must be shown, so far as possible, that diverticulosis is the only diseased state which is likely to be causing the symptoms.

The diagnosis of *diverticulitis* is less difficult when a tender sausage-shaped swelling can be felt in the left iliac fossa, especially if there is pain during or after evacuation, but must be established by radiography. The long history, the well-being of the patient in the intervals of symptoms, the absence as a rule of bleeding from the bowel or of much mucus are against malignant disease. The possibility of a left-sided appendicitis will be remembered; also of actinomycosis and pyosalpinx. When suppuration has occurred a differential diagnosis becomes of less importance, for the abscess must in any case be drained.

(*b*) As regards the *radiological diagnosis*, the prediverticular state must be distinguished from colitis. The latter causes inhibition or spasm without affecting the symmetry of the segments; the outline is smooth or any irregularities are nondescript. In the prediverticular state the symmetry is disturbed as above described, and if there is inhibition the irregularities show small twin convex impressions. Pericolic affections, such as tuberculosis, or inflammation where a jejunocolic fistula is threatening, may be indistinguishable in appearance from the prediverticular state.

The *established diverticula* are generally unmistakable. In a highly-placed mid-transverse colon where good oblique views are difficult to get, there may be *confusion with haustral residues*; these, however, will become less opaque as the bowel clears. In other parts it should be possible to get a view at the right angle to bring the suspected pouch into profile. A film should be taken after the lumen of the bowel is free from barium.

In *diverticulitis* the above-described rigidity and deformities of the bowel (from J to S) with a narrowed lumen are characteristic. Diverticula, sometimes new ones, will generally be seen near by. If growth occurs at a diverticulous area, the concave (fingerprint) encroachments on the lumen may be recognised.

Prognosis.

Were the outlook judged by the end-results of diverticulitis from the operating and post-mortem rooms of large hospitals[10] it would be grave indeed. A more hopeless condition to deal with than a suppurating sigmoid, involving and infecting surrounding parts, can hardly be thought of apart from active malignant disease. But, as we have shown above, diverticulosis may be quiescent over long periods of time. The cause of diverticulitis is inflammation in a pouch. What chance is there of preventing or allaying this? There is none unless the existence of the pouch is known. If every case of vague persistent or recurrent abdominal discomfort were investigated not only would diverticulosis but many other conditions be discovered at a stage when the most help can be given. The doctor's difficulty is that patients want the aches and pains to be cured by a bottle of medicine or a pill; and when such simple measures do not suffice the patient still would like to "wait and see how he gets on." The loss of health and efficiency from such delays is incalculable.

When a case of diverticulosis or early diverticulitis is recognised the prognosis is good, as a rule, for reasonable health and for life. The disease responds well to treatment. The graver complications occur chiefly in unrecognised or neglected cases. Both before and after inflammatory changes the physician and

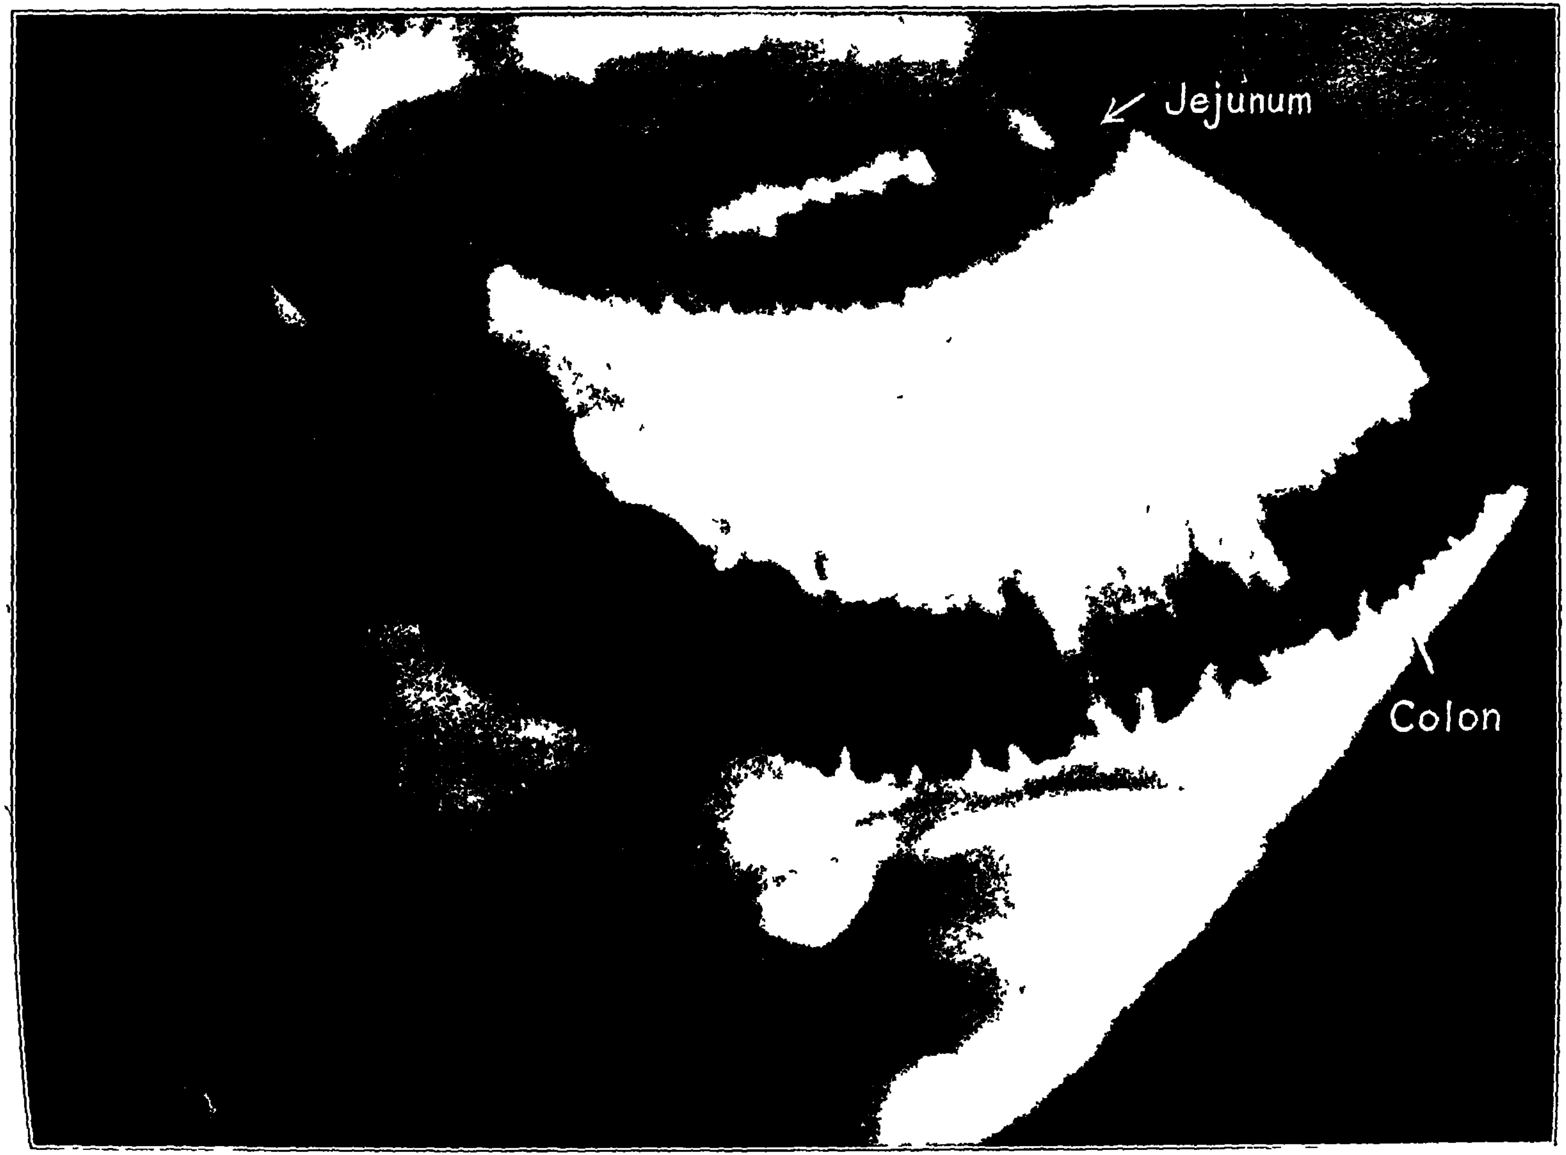
FIG. W.



Oblique view of a prediverticular state of the pelvic colon. Note the shallow convex impressions on both outlines, from the pelvic brim upwards. These are not to be confused with the deep serrations caused by spasm in other phases of the disease. Note also how the colon simulates the appearance of the normal small bowel. No diverticula yet present in the [illegible] bowel on the right; small early ones can be seen to the left near the pelvic brim.

single pocket, free from severe symptoms We did not know until this year that de Quervain,[8] the Swiss surgeon, had made the same proposal in 1914 in a paper not then accessible to us Any degree of irritation and inflammation arising in a pouch may logically be described as diverticulitis But in practice a distinctive term is needed for the later stage. which constitutes a definite and serious disease from which most of the subjects of diverticulosis never suffer.

The *clinical features of diverticulitis* are those of a low form of inflammation in the large bowel, usually in the left lower abdomen, spreading to neighbouring structures

Abdominal discomfort less often pain not as a rule related to food, is situated about or below the navel but especially in the left iliac fossa It may be intermittent, with intervals of several weeks or longer The pain may be severe, and is often accompanied by a general feeling of ill-health . it may take the form of a dragging sensation and backache General flatulence and a feeling of distension are usually mentioned and may be the only symptoms , an advanced state of diverticulitis may, indeed be present with but little complaint , in several there was no actual pain

Constipation, irregularity of the bowels, diarrhœa, or a sense of incomplete evacuation is frequent. The increasing constriction leads slowly. usually very slowly, to obstruction

In cases of implication of the bladder there may be *frequent micturition*, sometimes painful after the bowels are opened ; or a painless micturition may be followed by pain in the tumour.

A sausage-shaped *tumour* sometimes tender, but not always, can be felt in the left iliac fossa except in the very obese It may become acutely inflamed with pyrexia and vomiting Diverticulitis sometimes occurs at other parts of the colon.

Hæmorrhage, per rectum. excluding that from piles we have seen three times, but it is not usual. the inflammatory lesion lying as a rule without the mucous membrane

The *radiological features* of diverticulitis are definite With a barium meal or enema, typical rounded oval. or crescentic shadows of the barium in the diverticula will usually, though not always be recognised in the neighbourhood They are not, however, the characteristic features ; these, which we have already described above in detail. are the spike, or palisade-like projections of barium shadows from the lumen of the bowel, the wall of which is thickened (from inflammatory exudation) and fixed. Serial films, when superimposed, show no variation in the outline of the shadows although there may be vigorous and irritable contractions of the bowel wall above and below, or even in the same part of the gut opposite to the rigid area (See Fig Y on illustrative plate and Fig Z)

The *pathological features* are those of a chronic inflammation of the pelvic colon arising at first from one or more diverticula, but now involving all the coats of the gut. including, sooner or later, the peritoneal coat. and spreading to surrounding parts, especially to the bladder in men, but also, at times to the uterus ovary, small intestine, or abdominal wall An excellent description of the morbid histology will be found in Telling and Gruner's paper Leucocytosis is frequent In late stages small or sometimes larger. abscesses form in the inflamed or septic area Metastatic abscesses are unusual, but have been recorded

We put forward [9] the suggestion that the term diverticulitis should be reserved for those cases in which there is the combination of these three pictures —clinical, radiological, and pathological

Diagnosis

(*a*) *Clinical.*—Vague persistent or recurrent abdominal symptoms in a middle-aged well-nourished person, which are not accompanied by physical signs and do not yield to simple medicines such as carminatives or mild purges give rise to the suspicion of *diverticulosis* The diagnosis can only be established by an X ray examination of the bowel The recognition of diverticula is not enough as they may coexist with other lesions It must be shown. so far as possible, that diverticulosis is the only diseased state which is likely to be causing the symptoms.

The diagnosis of *diverticulitis* is less difficult when a tender sausage-shaped swelling can be felt in the left iliac fossa especially if there is pain during or after evacuation, but must be established by radiography. The long history, the well-being of the patient in the intervals of symptoms the absence as a rule of bleeding from the bowel or of much mucus are against malignant disease The possibility of a left-sided appendicitis will be remembered ; also of actinomycosis and pyosalpinx When suppuration has occurred a differential diagnosis becomes of less importance for the abscess must in any case be drained

(*b*) As regards the *radiological diagnosis*, the prediverticular state must be distinguished from colitis The latter causes inhibition or spasm without affecting the symmetry of the segments , the outline is smooth or any irregularities are nondescript In the prediverticular state the symmetry is disturbed as above described, and if there is inhibition the irregularities show small twin convex impressions Pericolic affections, such as tuberculosis or inflammation where a jejunocolic fistula is threatening, may be indistinguishable in appearance from the prediverticular state

The *established diverticula* are generally unmistakable In a highly-placed mid-transverse colon where good oblique views are difficult to get. there may be confusion with haustral residues : these however, will become less opaque as the bowel clears In other parts it should be possible to get a view at the right angle to bring the suspected pouch into profile A film should be taken after the lumen of the bowel is free from barium

In *diverticulitis* the above-described rigidity and deformities of the bowel (from J to S) with a narrowed lumen are characteristic Diverticula sometimes new ones, will generally be seen near by If growth occurs at a diverticulous area, the concave (fingerprint) encroachments on the lumen may be recognised

Prognosis.

Were the outlook judged by the end-results of diverticulitis from the operating and post-mortem rooms of large hospitals [10] it would be grave indeed. A more hopeless condition to deal with than a suppurating sigmoid, involving and infecting surrounding parts, can hardly be thought of apart from active malignant disease But as we have shown above diverticulosis may be quiescent over long periods of time The cause of diverticulitis is inflammation in a pouch What chance is there of preventing or allaying this ? There is none unless the existence of the pouch is known If every case of vague persistent or recurrent abdominal discomfort were investigated not only would diverticulosis but many other conditions be discovered at a stage when the most help can be given The doctor's difficulty is that patients want the aches and pains to be cured by a bottle of medicine or a pill ; and when such simple measures do not suffice the patient still would like to " wait and see how he gets on.' The loss of health and efficiency from such delays is incalculable.

When a case of diverticulosis or early diverticulitis is recognised the prognosis is good. as a rule for reasonable health and for life The disease responds well to treatment The graver complications occur chiefly in unrecognised or neglected cases Both before and after inflammatory changes the physician and surgeon can, between them, in a watched case, guard against or deal with any developments that are likely to occur. The accident of the rupture of a pouch into the general peritoneal cavity is uncommon, but most of us know of such cases. It has the same risks as any other perforation and is dealt with in the same way.

Treatment and Results

The medical treatment consists in keeping the body, the alimentary canal, and especially the colon, as healthy and clean as possible; any source of sepsis that can be reached must be removed. The diet should be simple and regular with a good deal of fruit and vegetables. We have described fully elsewhere[11] a diet which is found useful, but the preferences and state of each person must be considered. The bowels are kept regular by diet, paraffin, and especially by attention to habit; this can nearly always be done.

The colon is washed out with saline every other day, for a time, but at low pressure, the funnel being not more than 18 inches above the level of the anus. The fluid runs in at low pressure just as well as, or often better than, at higher pressure, which may provoke spasm. In no case, as we pointed out in our previous paper, should a diverticulous area be massaged. Only recently a man was admitted in whom a quiescent area had been awaked into subacute and painful diverticulitis by a course of massage given in ignorance of his state, with the object of curing the constipation.

We do not yet know to what extent repair may result after treatment of a prediverticular bowel. It is often considerable radiologically (cf Figs B and C) and in patients complaining of symptoms these may be entirely allayed. Sir Charles Gordon-Watson has described such a case[12] and we have seen others, one of which is mentioned under the heading Symptoms above. Our observations suggest that in all cases the affected part of the bowel is benefited and the progress of the disease delayed. Neither can we have proof that in the stage of established diverticula medical treatment—i e, paraffin, douching, removal of septic foci, and attention to general health, prevents the formation of stercoliths. We have, however, evidence that pouches empty their contents more readily after treatment, and stercolith formation would thereby be retarded if not prevented. In most cases the symptoms disappear as a result of treatment. In our series out of 158 patients with diverticulosis of all stages 87 complained of symptoms. Of these 70 were treated by us, 52 of whom were completely or almost completely relieved, 13 others received much benefit.

When *diverticulitis* is established the lavage is continued for longer, and in some cases permanently, at regular intervals. Enemas of 3–6 oz of warm olive oil are sometimes very useful. It is a great advantage to avoid, if possible, irritation, by regular purges, even a weekly dose of salts. But these must be used if there is a doubt about a sufficient evacuation.

Attention to the general habits of the patient is almost as important as the local treatment of the bowel. One reads, or hears doctors say, that the treatment is this or that. But hardly anyone, certainly no modern man over 30, can be treated entirely out of a book. He is nearly always working, playing, eating, drinking, smoking, or sitting too much, and unless his life be regulated the local measures will not be enough.

It is remarkable how quickly the inflammation may subside in subacute diverticulitis with the above measures. The symptoms may be gone in a week; and we have known a comparison of the radiograms after three weeks show that the lumen was restored almost to normal and the rigid area of bowel wall much lessened.

The patient must be warned about the danger of obstruction. If it threatens, the diagnosis of the degree of occlusion may be difficult. The practical point which has to be decided is whether colostomy shall be performed. The stoppage of diverticulitis can often be relieved even when there is a good deal of abdominal distension and constitutional disturbance. If grave symptoms such as a rising pulse-rate, collapse, and intractable vomiting are not present, and the diagnosis has been made radiologically, then castor oil (with laudanum and hot fomentations if pain is severe) and enemas may be given with confidence. A physical sign of value when improvement begins is the disappearance of resonance on percussion in the left lower quadrant. If, however, it has been found with X rays that there is much dilatation of the bowel above the affected area a colostomy is likely to be needed. But in most cases with continued care, even after severe obstruction, colostomy may be avoided for long periods, or indefinitely. One patient went 11 years after his first attack of obstruction until a colostomy was done; and that would probably not have been needed had he not been abroad and away from close medical supervision. Another had a first attack of obstruction eight years ago. He came under our observation two years later. This patient is still well with regular actions.

Surgical Treatment

Operation for obstruction from diverticulitis, perforation of a pocket, vesicocolic fistula, and suppuration in the bowel wall with involvement of surrounding structures, are necessary procedures at which the surgeon is an opportunist. He does what can be done.

How far can we control the disease so that these operations of despair may be avoided? The surgical treatment of a perforated pocket we cannot expect to avoid. The accident happens and must be dealt with; indeed it occurs when diverticulitis, as above defined, is not present. An operation for obstruction for a gradually closing irremovable infiltrated area, which cannot be otherwise mitigated, is also a necessity. It is better to do it, however, at a time of choice, when regular X ray observations have shown that the channel is narrowing and the bowel above dilating, and before the added dangers of actual obstruction have arrived.

When colostomy has been done the rest given to the collapsed area, aided by douching, may lead to a great degree of recovery. The swelling subsides and the lumen is restored. Sir Berkeley Moynihan has found it possible to close the colostomy again, in selected cases, to the great relief of the patients.

If, however, the case is recognised, adequately treated, and watched, with a barium enema every year for a simple diverticulosis, and every six months for diverticulitis, the severer complications are, in our experience, rare. The people who get into trouble are generally those whose cases have not been diagnosed, or who, after successful treatment, escape medical supervision and give less and less attention to the bowel as time passes.

Radical surgical treatment is sometimes possible. It is true that the disease tends to spread. But in practice hypertrophic inflammatory processes are generally confined to one area of bowel, and if that area can be successfully resected the patient is cured of diverticulitis. This has been done in a number of cases, as Mr Lockhart-Mummery[13] described recently. Gerzowitsch[14] has collected 101 from the literature. Of these 51 were cured, 7 died, and the result in 13 was not recorded. If the area can be radiographically defined, is not too low down, and is reasonably free from involvement of surrounding structures, and if the symptoms persist in spite of careful treatment, and the patient is in good condition otherwise, he may be offered exploration with a view to resection.

AN ANALYSIS OF THE CAUSES OF BLINDNESS

AMONG THE PUPILS OF THE SCHOOL FOR THE BLIND, SWISS COTTAGE

BY A HUGH THOMPSON, M D, B CHIR CAMB,
CONSULTING SURGEON TO THE WESTERN OPHTHALMIC HOSPITAL, LONDON

THE London Society for Teaching and Training the Blind has under its supervision about 500 blind individuals of whom, according to their latest report, 84 are between the ages of 5 and 16, all resident school-children at the Swiss Cottage Blind School, 62 pupils between 16 and 20, most of them resident either at the school or at the Girls' Hostel, and 47 adult pupils, besides upwards of 300 workers in shops and at home, who are able, either partially or (with the assistance that they obtain through the Society in accordance with the Blind Persons Act) wholly, to earn their own livelihood For the last seven years, as ophthalmic surgeon to the institution, I have had an opportunity of examining all the pupils and some of the out-workers, and the present paper is an attempt to analyse the causes of their blindness.

Degrees of Blindness

Blindness is a term which needs definition Only a small proportion of these cases were without the power of perceiving a light when held before their eyes (or eye) Most of them could recognise whether a hand held in front of them was moving or not Many of them could count the fingers of a hand held up two or three feet in front of them Some of them could see the largest letter of the ordinary test type at the distance of 6 metres (6/60) A few of them could see better than this

It is well known that the acuity of central vision is not a wholly sufficient test for the presence or absence of blindness The visual field may be so small that even with comparatively good central acuity the patient ought to be considered blind in the economic sense This may occur in glaucoma (which, in children, takes the form of buphthalmos), in optic atrophy, and in retinitis pigmentosa In all three of these, moreover, the disease is, as a rule, slowly but surely progressive, so that even if the patient is not blind at the time of examination he or she is in imminent danger of becoming so, and, in the case of children, it is wise to educate them, bearing in mind that eventuality This last consideration also applies to certain cases of high myopia about which I shall say more later

Classification of Cases under Survey.

The total number examined by me was 255, of whom 150 were males and 105 females, 51 of whom had vision better than 6/60 with full fields, the remainder coming under the definition of blindness recently suggested by the Ministry of Health Except 16 they were all under 25 years of age The following is an analysis of these cases in respect of (1) the causes and (2) the extent of their blindness

1 *Ophthalmia Neonatorum*

57 examined 28 males, 29 females

Vision—No p l	16	Vision—6/60	6
p l	20	Better than 6/60	4
Counting fingers	10	Uncertain	1

It will be seen that the degree of blindness among these cases is very extreme In five of the cases one eye had been excised In two both had been excised In most of them the corneæ were unsightly from a dense whitish opacity In some cases the whole globe was shrunk In some it was bulging There was cataract in many, and practically all had nystagmus

2 *Optic Atrophy*

37 examined 25 males, 12 females

Vision—No p l	7	Vision—6/60	3
p l	19	Better	2
Fingers	5	Uncertain	1

In these cases the outward appearance of the eyes is generally normal except for the pupils which often do not react to light Nystagmus is rare since in most of these cases the patients have had sight and acquired the art of fixation in infancy. The causation was as follows —

1	Congenital syphilis	8
2	Cerebral (one each of dystrophia adiposo genitalis, cerebral abscess, cerebral tumour, oxycephaly, and vascular lesion at birth)	5
3	Familial	5
4	Following disease (one meningitis, one measles and pneumonia)	2
5	Accident (fractured base)	2
6	Uncertain	15

3 *Syphilis*

30 examined · 11 males, 19 females These included (1) interstitial keratitis, with or without choroiditis, 24, (2) choroiditis, without interstitial keratitis, 6 The vision of these cases was better than that of the previous groups

Vision—No p l	1	Vision—6/60	3
p l	1	Better	11
Fingers	14		

Three-quarters of these children were cases of interstitial keratitis, a disease which, though it often causes temporary blindness lasting from three months to two or three years, does not, as a rule, cause permanent blindness The disease, however, is relatively common and the exceptions who become blind are sufficiently numerous to form a notable proportion of the inmates of all blind schools In many cases the interstitial keratitis is complicated by choroiditis, cyclitis, or cataract, which partially accounts for the number of those who become permanently blind On the other hand, it is not infrequent for children whose vision has been given up as hopeless to be admitted to the blind school and improve to some extent in the course of years

4 *Congenital Cataract*

31 examined 20 males, 11 females

Vision—No p l	3	Vision—6/60	7
p l	3	Better	8
Fingers	10		

All these cases, without exception, had been operated on, but many at an age when, nystagmus having already been established, the power of central fixation could not be acquired Probably in some cases blindness might have been prevented by more timely operative treatment Many of these cases had capsule or secondary membrane over the pupil and in three of these it was possible to restore fairly good sight (6/18), and in one other moderate sight (6/60) by needling operations after they had already been admitted to the school as blind In another case where four needling operations had been performed at the age of 15 and an absolutely clear pupil had been obtained the vision was no better than 5/36, nystagmus being present and the eye partially amblyopic Besides nystagmus and thick membrane, complications in these cases included microphthalmos, high myopia, cyclitis, and detached retina

5 *Congenital Cases other than Cataract*

34 examined 20 males, 14 females

Vision—No p l	2	Vision—6/60	5
p l	7	Better	6
Fingers	14		

The conditions found were as follows —

—	Male	Female	Total
Albinism	6	5	11
Dislocated lens with high myopia	2	—	2
Congenital nystagmus without discoverable fundus change	7	3	10
Microphthalmos	2	1	3
Aniridia	2	3	5
Macular coloboma	1	1	2
Dense capsular pupillary membrane complicated with congenital syphilis	—	1	1

In this group, as in the preceding one, the preponderance of male over female cases will be noted Albinism, as is well known is a family disease Out of the six boys in the school blind from this condition there are two pairs of brothers Practically all of these congenital cases have nystagmus Ten of them I have put down as congenital nystagmus without discoverable fundus disease sufficient to cause blindness though in at any rate one of these there were visible choroidal changes The examination of the macula, however, in these cases is peculiarly difficult This also applied to cases of aniridia, all of whom had nystagmus Absence of the iris in itself would not cause blindness, and the presumption is that all cases of albinism aniridia and congenital nystagmus which are severe enough to cause blindness do so on account of some defect in the macula which may or may not be visible to the ophthalmoscope

6 *Disease*

37 examined 25 males, 12 females

I will subdivide this group (1) Retinitis pigmentosa, 11 cases of whom all but one were males This proportion is an exaggeration of that generally found Nettleship puts the proportion of males in affected families as only about 60 per cent (Trans Oph Soc, 1909) A definite family history was obtained in six of my cases

Vision—No p l	1	Vision—6/60	3
p l	3	Better	1
Fingers	3		

In addition to the bad central vision, the contraction of the fields and the inevitably progressive nature of the disease are such that even those whose central acuity in childhood is fairly good should certainly be educated in a blind school

(2) Keratitis, iritis, cyclitis, choroiditis, and panophthalmitis 19 cases, 10 males and 9 females

Vision—No p l	6	Vision—6/60	2
p l	3	Uncertain	1
Fingers	7		

In most of these cases the causation was uncertain Congenital syphilis may account for some Measles was the cause assigned in four cases, the blindness having followed the disease at the ages respectively of 2 years, 15 months, 2 years, and 3 years In one of these cases both eyes were shrunk In another both had been excised There was one case of panophthalmitis following scarlet fever at the age of 14 months, and one case of iridocyclitis following influenza One case of keratitis was due to trichiasis

(3) Besides the above, the group includes three cases of buphthalmos, one of cerebral blindness without optic atrophy, two of double detached retina, and one in which both eyes had been excised without obtainable history None of these cases had any vision better than counting fingers

7 *Accident*

Eight cases, all males six of them cases of sympathetic ophthalmia, in none of which was the vision better than counting fingers The other cases were one in which an accident occurred to the only good eye at the age of 8, the other one having been blinded by cyclitis at the age of 2, the other in which the first eye was blinded by an accident at the age of 7, and the second eye by another accident at the age of 15, both having been excised These two cases are exceptional, and illustrate the chief value of the possession of two eyes

8 *Myopia*

21 cases 13 males 8 females

Vision—No p l	1	Vision—Better	10
Fingers	4	Too young to take vision	4
6 60	2		

As a rule these cases are much more suitable for the myope classes such as have been established by the L C C than for the blind school The great majority of high myopes never become blind, but there are cases where the damage to the macular region has already reached such an extent, even in childhood, and there are others where even without this being obvious the degree of myopia in relation to the age of the child is so high, that it is on the whole wiser, in view of the child's probable future, that he should be brought up in a blind school Of those whose corrected central acuity was no better than 6/60 five had macular choroiditis and one double detached retina This last, however, was an adult pupil of 42, and the case illustrates one of the dangers to which these children are liable when they get older. Most of them when young have healthy fundi. Unfortunately in country districts and in most towns there is no "myopic class" available, and the question has to be decided, not what is best for the child but what is second best, an ordinary school or a blind school It thus happens that pressure is often brought on the authorities of the blind schools to admit children to be trained in a way which is not the ideal one for them

The Preventive Point of View

From the point of view of prevention, it is worth while to classify these cases according to their causation in a somewhat more general way For this purpose I will exclude all those whose vision is better than 6/60 except in the three progressive diseases already referred to This leaves 213 cases, which I will classify under the following heads

1 Caused by venereal disease in the parents, 80, of which—

Ophthalmia neonatorum	53
Syphilitic keratitis and choroiditis	19
Syphilitic optic atrophy	8

This is probably an understatement as far as syphilis is concerned It is probable that some of the cases of optic atrophy of uncertain causation and some of the cases of cyclitis were due to syphilis.

With regard to ophthalmia neonatorum, it may be objected that not all cases of this disease are due to gonorrhœa This, of course, is perfectly true. According to the report on blindness in Glasgow, published in 1926, and compiled by Drs Freeland Fergus and J L Halliday, the number of cases of ophthalmia neonatorum notified during the years 1912–24 inclusive was 7687 Of these, swabs were taken in 1791 cases, of which only 31 3 per cent were positive for the gonococcus On the other hand the number of those blinded by the disease—i e, with both eyes blind—out of 3501 non-gonococcal cases was *none*, whereas out of the 1265 gonococcal cases it was six It may therefore be fairly assumed that when a patient is blinded in both eyes the gonococcus is responsible, and this applies to all the cases at the blind school

The possibility of prevention lies in (1) the reduction among the general population of the habit of promiscuous sexual intercourse; (2) the prophylactic treatment of ophthalmia of the new-born by means of the more rigid enforcement of notification by midwives, greater facilities for immediate skilled treatment of the disease without loss of time and possibly the more general use of prophylactic drops of nitrate of silver or some substitute by midwives (3) the increase of the systematic treatment of venereal disease which has already been established, (4) a wider knowledge among the general population of the facts

2 Cases caused by congenital and inherited conditions other than syphilis, 66

Cataract	25	Family choroiditis	2
Other congenital conditions	25	Family optic atrophy	3
		Retinitis pigmentosa	11

As regards prevention, I cannot help noticing the number of cases of congenital cataract who, in spite of having been operated on, remain blind or partially blind Most of these cases have more or less capsule obstructing the pupil, but some of them have a good clear pupil and yet they are blind They practically all have nystagmus, and this points to the reason why even with a good pupil and a convex lens in place of the crystalline which has been removed they still see so badly Operative treatment is often undertaken too late after the period of infancy during which alone it is possible to attain the power of correct central fixation When once the bad habit of nystagmus has been acquired there is little chance of good vision ever being restored Undoubtedly for these cases prevention of a certain amount of blindness could be attained if competent ophthalmic treatment was undertaken sufficiently early in life

3 Cases caused by non-venereal disease other than family and inherited, including optic atrophy not due to these causes and also including myopia, 57

With regard to prevention, there is little to be said. Myopia which is so malignant as to cause blindness in early life can hardly be prevented Prevention of blindness in later life by an appropriate regime for youthful myopes is another matter.

Measles as a cause of blindness is emphasised in the Glasgow report when the percentage, based on the accounts given by the parents, is put down as 2 9 Our cases estimated in the same way come to 5, or 2 3 per cent

4 *Accident* —10 cases, including two optic atrophy cases As to the others, I have been struck with the fact that the air-gun is a most dangerous toy for boys Accidents, however, do not happen to both eyes at once In nearly all these cases blindness was due to sympathetic ophthalmia, and as, with timely hospital treatment, this disease is becoming exceedingly rare, we may hope that in the future these cases may almost be reduced to nil

Reducing these causes of blindness to percentages we get—

Venereal disease	80	or	37 6	per cent
Inherited and family disease	66	,,	31 0	,,
Non inherited and non venereal disease	57	,,	26 7	,,
Accident	10	,,	4 7	,,

Clinical and Laboratory Notes.

A CASE OF COR TRILOCULARE BIATRIA

BY EDITH F W MCCREA, M B DUB , F R C S IREL ,

PHYSICIAN TO THE MANCHESTER BABIES' HOSPITAL

THE following instance of cardiac malformation appears worthy of record

A female infant, aged ten weeks, was admitted to hospital on Jan 28th, 1926, with a history of dyspepsia She was the only child of her parents, and was born at full time, there was no family history of importance

On admission she was a very small, wasted child, weighing 5 lb 8 oz., cyanosis was marked and there was a loud systolic murmur, audible all over the præcordia and propagated into the left axillary and scapular regions The Wassermann and von Pirquet reactions were negative

The infant suffered from a mild form of chronic dyspepsia, but the clinical picture was primarily that of a cardiac lesion The cyanosis varied in degree from time to time, but was always present the appetite was poor and the child was extremely listless For six weeks her general condition did not materially alter; then a rapid deterioration developed and death occurred within a few days

Post-mortem examination revealed an interesting condition of the heart On opening the pericardium the heart appeared at first glance to be normal in size and appearance But on tracing the vessel, which seemed from its site of origin to be the pulmonary artery, it proved to be the aorta, which gave off its usual branches. Lying posteriorly to this vessel in the normal position of the aorta was the pulmonary artery, the diameter of which was about one-third that of the aorta

The ductus arteriosus was not patent, the right and left atria were normal except for the presence of a patent foramen ovale and the atrioventricular valves appeared to be normal and competent A single ventricle was present, from which both aorta and pulmonary artery originated. The interventricular septum was deficient and no portion of it could be identified although two large fleshy bands partially subdivided the cavity The aortic orifice lay at the site usually occupied by that of the pulmonary artery, while the latter vessel with its thin walls lay posteriorly and to the left in the normal position of the aorta, each orifice possessed three semilunar valves

The principal defect in this heart was apparently a total deficiency of the interventricular septum, together with malformation of the proximal bulbar septum which resulted in transposition of the great vessels In Vierordt's classification, quoted by Abbott in Osler and McCrae's "System of Medicine" (vol iv , p 370), this case would be grouped under the heading of "Cor Triloculare Biatria" with "partial transposition, in which both great vessels arise transposed from a common ventricle"

I reported another example of cor triloculare biatria in 1923[1] in an infant aged 3 months This heart apparently resembled those quoted by Holmes (see Abbott), and also one described by Keith, in that an anomalous septum was present; there was however, no transposition of the great vessels True cor triloculare biatria is stated to be an extremely rare condition but I have seen two cases within three years

I am indebted to Dr. Florence Robinson for permission to publish this case

A CASE OF SQUAMOUS CELLED EPITHELIOMA OF THE BRONCHUS

ILLUSTRATING LYMPHATIC PERMEATION

BY D. M BADEN EVANS, M B , M R C.P. LOND ,

RESIDENT MEDICAL OFFICER, BOLINGBROKE HOSPITAL

THE following case of epithelioma of the right bronchus is of interest in view of the widespread metastases, unusual in this type of tumour, the clearly defined mode of spread, and the deceptive nature of its clinical harbinger; also on account of the squamous type of cell seen in a tumour arising from a tube, normally lined by columnar epithelium.

The patient, a feebly nourished man of 54, came up complaining of a "boil" on the right side of the back. On inspection the tumour was of the size and shape of a split walnut, situated opposite the second dorsal spine It had been incised three weeks previously, but had failed to heal The mass was indurated and fungating, and hard glands were palpable in both axillæ and supraclavicular areas There was also a small enlargement of the lower end of the left ulna

Examination of the chest revealed râles and rhonchi all over, which was consistent with a history of several years of chronic bronchitis But a little exaggerated dullness over the root of the right lung prompted the taking of an X ray photograph, and this strongly suggested the presence of a new growth

The tumour on the back was excised under local anæsthesia and was found to have no deep attachments whatsoever A gland from each axilla was also removed for section All three were shown to be involved by squamous-celled epithelioma There was no keratinisation however, and the cell-nests of cutaneous tumours were absent Three weeks later the patient's "bronchitis" became worse, expectoration became profuse, and later hæmorrhagic, the temperature remitted between 100° and 103° F., and cyanosis with œdema of the neck and face developed In five days the patient died.

Autopsy revealed a large growth of the right bronchus firmly adherent to the spinal column from which it could be separated only with the scalpel. There were secondaries in the mediastinal glands, the cœliac glands, the glands along the curvatures of the stomach, there was one small growth in the liver, and one in the periosteum at the lower end of the left ulna. From its size, age, and involvement of surrounding structures the primary growth was obviously in the right bronchus The squamous type of cell must have evolved from the columnar by a process of metaplasia consequent on prolonged inflammatory irritation There were elsewhere abundant evidences of chronic bronchitis and bronchiectasis with atrophy of the lining of the respiratory tubes and thickening around

Sections were made from all the secondary deposits which were found to be involved by the same type of growth Their situation admirably illustrates the centrifugal manner of spread by the lymphatics · (a) To the back along the lymphatics accompanying the dorsal branches of the intercostal vessels (b) Forwards to the mediastinal glands (c) Upwards in along the thoracic duct, and tributaries of the right lymphatic duct, to the supraclavicular glands, and thence to the axillary glands (d) Downwards, along the thoracic duct to the cœliac glands and those of the stomach

---

[1] Willock THE LANCET, 1923, ii, 1399

The small deposits in the liver and ulnar periosteum were probably the result of spread by the blood stream from emboli entering by the large lymph trunks If the metastasis in the ulna were due to permeation from the axilla, it would have to be assumed that perilymphatic fibrosis had prevailed in the interspace

My thanks are due to Mr V Zachary Cope for permission to publish this case

---

A NOTE ON
GIDDINESS IN NEURASTHENIA

By Hector M Walker, M D Glasg

Vertigo is a symptom commonly met with in practice, and it is usually very persistent and difficult to deal with It may arise in many and varying conditions, and a difficulty that it presents is that it is rarely easy to come to a clear understanding of what the patient means by giddiness The giddiness complained of by the neurasthenic appears to be mainly an uncertainty of himself in relation to his surroundings and a feeling that he may fall at any time The so-called gastric vertigo is usually of the same nature, but there is often a more definite feeling of subjective or objective movement than in the neurotic type

Vertigo in a Boy Relieved by Irrigation of the Meatus

Irrigation of the external meatus of the ear with hot or cold water normally produces a certain train of events, evidenced by vertigo, a tendency to fall to one side, nystagmus, and past-pointing The vertigo, nystagmus, past-pointing, and falling occur in a definite direction, and the direction differs when hot water is used from that when cold is used, and the response from the left ear is in the opposite direction to that of the right This reaction was described by Barány, and it occurred to me to use it to gain some information on the symptom of vertigo in cases in which I had been unable to find an organic cause

A boy of 11 years had suffered for eight months from very severe headaches of a migrainous type coming on at intervals of two to three weeks The headache was always ushered by a subjective sense of giddiness which would last for 10–15 minutes and was invariably followed by a headache lasting for several hours The vertigo was not associated with nystagmus, past-pointing, or a staggering gait, the face turned pale but he did not vomit The absence of these objective signs suggested that there was no disease of the labyrinths

At one time when I happened to see him at the beginning of an attack I decided to test the vestibular reaction, and also to see what the effect of a powerful physiological stimulus to vertigo would be I therefore syringed his left ear with cold water and immediately he developed a very marked nystagmus, felt extremely giddy, and vomited The pallor gave way to a flush on the cheeks In about a minute the vertigo left him and the headache which always followed the vertigo did not develop

The disturbance in this case evidently started with an aberrant flow of neural energy in the vestibular nucleus giving rise to the sense of vertigo, through the cerebellar connexions of the nucleus The headache which followed the vertigo was probably originated by an overflow into the adjacent trigeminal nucleus, the outlet through the trigeminal nucleus being an easier path, as it is one normally concerned with somatic sensation By giving a stimulus sufficiently powerful to overcome the aberrant flow and to act as a prepotent stimulus, a normal reaction is provoked, with a normal outlet preventing overflow into the trigeminal nucleus

Five Similar Cases

Five other cases were of neurasthenics, who complained of giddiness This giddiness, so far as I could make out consisted of an uncertainty of themselves in relation to their surroundings, and a feeling that they might fall at any time if they did not use every means to keep a strict hold on themselves I had the idea that this symptom was due in part to a deficient action of the proprioceptive system through the state of nervous exhaustion, and I decided to try the effect of vestibular stimulation

In a man of 36, who complained of persistent giddiness the reaction was delayed for two minutes The vertigo was not very severe, and the reaction was normal in direction, but the nystagmus was rather sluggish

The second patient was an intelligent man of 35 I placed him in a chair facing an open window and irrigated his ear with cold water This quickly produced a normal reaction with very marked vertigo and nystagmus He said that he felt much better after this and that he felt more confidence on his way home than he had had for six months I repeated the process twice and the condition cleared up completely A year later he returned with the request to have it done again as he was beginning to have a return of the giddiness, and after one irrigation he said that it had gone

The influence of the vertigo stimulus probably acted partly by re-establishing his confidence when he saw what real vertigo meant The principal effect I think, depended upon the replacement of the aberrant flow of neural energy in the nucleus by a prepotent stimulus which took a normal path

The next case, that of a man of 30, was of special interest, for although the giddiness disappeared after two irrigations which gave a normal reaction, it was replaced by a headache strictly limited to the right side—the side that I had irrigated For five weeks he had occasional headaches, but they cleared up as his general condition improved The powerful stimulus caused a normal flow of neural energy in the vestibular nucleus, and the aberrant excitation, instead of being overcome as in the case of the boy, was here directed into the trigeminal nucleus The stimulus which affecting the vestibular nucleus will cause vertigo in the trigeminal nucleus may cause headache, and in the vagal nucleus may cause vomiting The gastric vertigo is probably a reversal of this process, the stimulation referred back to the vagus nucleus overflowing into the vestibular nucleus The headache sometimes associated with this disturbance may be a like involvement of the trigeminal nucleus

The condition of the other two patients was also improved by the stimulation, although one, who had complained of giddiness for nine months, required irrigation six times at intervals of five days He also returned some months later with a request to have the treatment repeated

The vestibular nucleus and the cerebellum, which is really in phylogeny an outgrowth and development of the part of the vestibular system known in fishes, as the acustico-lateral area, are the head ganglia of the proprioceptive system It is easy to understand that even a slight functional disorder of this system, which normally acts automatically will call into action a continual slight activity of a conscious element for postural control through the cortico-spinal tracts This must necessarily absorb a considerable amount of nervous energy, and it is not surprising that such cases have marked symptoms of neurasthenia which resist treatment

I believe that this method throws some light upon a certain type of giddiness, although it is obvious that in these cases there is not a true vertigo The few cases that I have examined were carefully selected as it was this particular symptom, occurring in neurasthenia, that I wished to study

Medical Societies.

ROYAL SOCIETY OF MEDICINE

SECTION OF SURGERY: SUBSECTION OF PROCTOLOGY

A MEETING of this Subsection was held on May 11th, Mr. J. P. LOCKHART-MUMMERY, the President, in the chair.

Mr. W. E. MILES opened a discussion on

COLOSTOMY

He began by describing the lumbar colostomy of preantiseptic days, when the surgeons were afraid to approach the bowel intraperitoneally. The chief defect of this measure was that the stoma in the colon was lateral and did not stop the passage of fæces beyond it. It had one virtue—protrusion of the mucosa never occurred. Now that resection with anastomosis could be performed, the operation of colostomy was needed only for inoperable carcinoma of the rectum or pelvic colon; lumbar colostomy had been gradually superseded by sigmoidostomy. At first this was made a little above the left Poupart's ligament and at about the middle of the pelvic loop, and an opening was made in the parietes large enough to put the hand in for investigation. The result was that the spur receded so that the opening became a lateral one with all the defects of the lumbar colostomy combined with considerable protrusion. Later Mr. Harrison Cripps had pointed out that protrusion could be prevented by making the opening high up in the pelvic colon. Much controversy had followed; the advocates of the low opening said that it was necessary to preserve a natural reservoir which more or less controlled defæcation. They forgot that, whereas Nature provided a loop for control she had also provided an efficient lock in the form of the sphincter. Mr. Miles had no doubt that Harrison Cripps was right about the site of election. The essential feature of a colostomy should be that it effectively prevented the contents of the bowel from passing beyond the stoma into the loop below. For this the permanence of the spur was essential. If the mesentery were short, congenitally or as a result of carcinomatous infiltration, it was impossible to deliver a loop long enough to make a good spur, and directly the rod was removed the spur would recede on the slightest tension from within.

Some had thought that peristalsis had something to do with recession of the spur and had therefore divided the bowel completely, making a terminal colostomy. In cases for which colostomy was now performed, however, the distal portion could not be occluded because of discharges from the growth. Mr. Miles's objection to this device was that division of the bowel created a weak spot between the two openings and sometimes large hernial sacs appeared between them. Another modification was to make the colostomy opening through the outer border of the rectus muscle. This gave good support but could only be done where there was sufficient length of loop of the pelvic colon. It did not, in fact, matter what method was adopted so long as the colostomy was effective.

Indications

Cæcostomy was a lateral opening, a temporary measure only, for evacuation, washing out, or forming a safety-valve. Transverse colostomy was a substitute for sigmoidostomy when the latter was impossible. The indications were carcinoma of the rectum or lower sigmoid, to give rest in inflammatory conditions, such as diverticulitis, to overcome obstruction in cases of compression from without, for congenital defects and for relief of fistulæ or of irremediable incontinence after operations for fistula. Mr. Miles did the operation one-third along the line from the anterior superior spine to the umbilicus, and he chose that part of the pelvic colon which was best and not where chance dictated. Most of the patients were elderly with some visceroptosis, and the colon was usually bound down by altered peritoneal attachments, so the abdomen should be opened down the middle line and the gut mobilised if necessary. A stab incision was then made in the parietes and a circle of skin of about 1 inch in diameter removed so that when the bowel was extruded it adhered to the aponeurosis of the external oblique thus preventing recession. A ligature was then introduced through the mesentery, passing first close to the proximal end and then to the distal, to anchor it to the skin. A loop of silkworm-gut was drawn tightly enough to obstruct venous return, but not arterial flow, so that a solid œdema was produced in the spur, which looked like a tomato and was shaped like a mushroom. The spur so produced was durable; he had recently seen a case done in 1903. Much depended on careful after-treatment: daily washing out of the bowel, and the use of a cap as a protector; a bag was the worst possible thing, as it produced a negative pressure which led to protrusion.

Mr. W. B. GABRIEL said that a permanent colostomy was now regarded as an essential part of the operation for carcinoma recti, and it could be one of the most satisfactory operations in surgery. It must not be regarded as a crippling process; patients were able to take part in their usual social lives and pursuits as before. His remarks would deal with colostomy of the pelvic colon with the bowel in continuity, and the indications for this measure were: 1. Carcinoma of the rectum, whether operable or inoperable. Nearly every case benefited if the operation were done in good time; failure might be due to faulty technique or inability of the patient to adapt to the new conditions. 2. Fibrous stricture too extensive or too high for dilatation. 3. Diverticulitis, causing obstruction or vesico-colic fistula. 4. Acute spreading ulceration—a very rare indication. 5. Recent injuries of the rectum, such as gunshot wounds, where it was a useful adjunct to local drainage and older injuries where extensive plastic operations were required. 6. Compression by extrarectal tumours, such as pelvic sarcoma and chondroma or, more commonly, carcinoma of the cervix uteri.

The Rectus Incision

Mr. Gabriel's technique, and that commonly followed at St. Mark's Hospital, began with a vertical incision 1½ inches long to the left of the midline, splitting the fibres of the rectus abdominis. The advantages of this method were that a general exploration could easily be done, that it was less likely to produce ventral hernia, and that the transverse colon was available if required. He had tried fancy incisions, such as those designed to give a bridge of skin between the stomata, and had found no advantage in them. A glass rod was better for fixing the bowel than a stitch, which was liable to cut out. It should be passed through the mesentery ½ inch to 1 inch from the edge of the bowel and must be left in for 14 days at least. Nothing but catgut was used for the abdominal wall, and all sutures were interrupted. Tension sutures were put through the skin and anterior sheath. The difficulty of bringing the bowel to the surface was generally met by thorough division of adhesions.

Complications and Their Prevention

He quoted figures from St. Mark's Hospital where, out of 259 colostomies for inoperable carcinoma of the rectum, the immediate mortality had been 13.5 per cent., 20 cases having died of heart failure, exhaustion, or pulmonary complications, four of peritonitis, one from strangulation of a loop of small intestine between the colostomy and the abdominal wall, one each from renal failure, coma, and hæmorrhage from the proximal end, while four more remained distended without obvious reason. Later complications were stenosis always at skin-level; retraction of the spur, which must be actively treated by dissecting out and refixing; proximal or distal prolapse due to too large-growth. Their situation admirably illustrates the centrifugal manner of spread by the lymphatics: (a) To the back along the lymphatics accompanying the dorsal branches of the intercostal vessels. (b) Forwards to the mediastinal glands. (c) Upwards in along the thoracic duct and tributaries of the right lymphatic duct to the supraclavicular glands; and thence to the axillary glands. (d) Downwards along the thoracic duct to the cœliac glands and those of the stomach.

The small deposits in the liver and ulnar periosteum were probably the result of spread by the blood stream from emboli entering by the large lymph trunks. If the metastases in the ulna were due to permeation from the axilla, it would have to be assumed that perilymphatic fibrosis had prevailed in the interspace.

My thanks are due to Mr. V. Zachary Cope for permission to publish this case.

A NOTE ON
GIDDINESS IN NEURASTHENIA.

By HECTOR M. WALKER, M.D. GLASG.

VERTIGO is a symptom commonly met with in neurasthenia, and it is usually very persistent and difficult to deal with. It may arise in many and varying conditions, and a difficulty that it presents is that it is rarely easy to come to a clear understanding of what the patient means by giddiness. The giddiness complained of by the neurasthenic appears to be mainly an uncertainty of himself in relation to his surroundings and a feeling that he may fall at any time. The so-called gastric vertigo is usually of the same nature, but there is often a more definite feeling of subjective or objective movement than in the neurotic type.

Vertigo in a Boy Relieved by Irrigation of the Meatus.

Irrigation of the external meatus of the ear with hot or cold water normally produces a certain train of symptoms, evidenced by vertigo, a tendency to fall to one side, nystagmus, and past-pointing. The vertigo, nystagmus, past-pointing, and falling occur in a definite direction, and the direction differs when hot water is used from that when cold is used, and the response from the left ear is in the opposite direction to that of the right. This reaction was described by Barany, and it occurred to me to use it to gain some information on the symptom of vertigo in cases in which I had been unable to find an organic cause.

A boy of 11 years had suffered for eight months from very severe headaches of a migrainous type coming on at intervals of two to three weeks. The headache was always ushered in by a subjective sense of giddiness which would last for 10–15 minutes and was invariably followed by a headache lasting for several hours. The vertigo was not associated with nystagmus, past-pointing, or a staggering gait; the face turned pale but he did not vomit. The absence of these objective signs suggested that there was no disease of the labyrinths.

At one time when I happened to see him at the beginning of an attack I decided to test the vestibular reaction, and also to see what the effect of a powerful physiological stimulus to vertigo would be. I therefore syringed his left ear with cold water and immediately he developed a very marked nystagmus, felt extremely giddy, and vomited. The pallor gave way to a flush on the cheeks. In about a minute the vertigo left him and the headache which always followed the vertigo did not develop.

The disturbance in this case evidently started with an aberrant flow of neural energy in the vestibular nucleus, giving rise to the sense of vertigo, through the cerebellar connexions of the nucleus. The headache which followed the vertigo was probably occasioned by an overflow into the adjacent trigeminal nucleus, the outlet through the trigeminal nucleus being an easier path as it is one normally concerned with somatic sensation. By giving a stimulus sufficiently powerful to overcome the aberrant flow and to act as a prepotent stimulus, a normal reaction is provoked, with a normal outlet preventing overflow into the trigeminal nucleus.

Five Similar Cases.

Five other cases were of neurasthenics who complained of giddiness. This giddiness, so far as I could make out, consisted of an uncertainty of themselves in relation to their surroundings, and a feeling that they might fall at any time if they did not use every means to keep a strict hold on themselves. I had the idea that this symptom was due in part to a deficient action of the proprioceptive system through the state of nervous exhaustion, and I decided to try the effect of vestibular stimulation.

In a man of 26, who complained of persistent giddiness, the reaction was delayed for two minutes. The vertigo was not very severe, and the reaction was normal in direction but the nystagmus was rather sluggish.

The second patient was an intelligent man of 35. I placed him in a chair facing an open window and irrigated his ear with cold water. This quickly produced a normal reaction with very marked vertigo and nystagmus. He said that he felt much better after this and that he felt more confidence on his way home than he had had for six months. I repeated the process twice and the condition cleared up completely. A year later he returned with the request to have it done again as he was beginning to have a return of the giddiness, and after one irrigation he said that it had gone.

The influence of the vertigo stimulus probably acted partly by re-establishing his confidence when he saw what real vertigo meant. The principal effect, I think, depended upon the replacement of the aberrant flow of neural energy in the nucleus by a prepotent stimulus which took a normal path.

The next case, that of a man of 30, was of special interest, for although the giddiness disappeared after two irrigations which gave a normal reaction, it was replaced by a headache strictly limited to the right side—the side that I had irrigated. For five weeks he had occasional headaches, but they cleared up as his general condition improved. The powerful stimulus caused a normal flow of neural energy in the vestibular nucleus, and the aberrant excitation, instead of being overcome as in the case of the boy, was here directed into the trigeminal nucleus. The stimulus which, affecting the vestibular nucleus will cause vertigo, in the trigeminal nucleus may cause headache, and in the vagal nucleus may cause vomiting. The gastric vertigo is probably a reversal of this process, the stimulation referred back to the vagus nucleus overflowing into the vestibular nucleus. The headache sometimes associated with this disturbance may be a like involvement of the trigeminal nucleus.

The condition of the other two patients was also improved by the stimulation, although one, who had complained of giddiness for nine months, required irrigation six times at intervals of five days. He also returned some months later with a request to have the treatment repeated.

The vestibular nucleus and the cerebellum, which is really in phylogeny an outgrowth and development of the part of the vestibular system known in fishes as the acustico-lateral area, are the head ganglia of the proprioceptive system. It is easy to understand that even a slight functional disorder of this system, which normally acts automatically, will call into action a continual slight activity of the conscious element for postural control through the cortico-spinal tracts. This must necessarily absorb a considerable amount of nervous energy, and it is not surprising that such cases have marked symptoms of neurasthenia which resist treatment.

I believe that this method throws some light upon a certain type of giddiness, although it is obvious that in these cases there is not a true vertigo. The few cases that I have examined were carefully selected as it was this particular symptom, occurring in neurasthenia, that I wished to study.

ROYAL SOCIETY OF MEDICINE: CLINICAL SECTION.

A MEETING of this Section was held on May 13th Sir HERBERT WATERHOUSE, the President, in the chair

Mr PHILIP TURNER showed a case of

Gumma of Liver.

The patient was a man aged 34, who had been admitted to hospital suffering acute abdominal pain He was said to have had right iliac and hypogastric pain for six years, particularly after taking food On the day of admission the symptom was specially acute, with rigidity of the upper abdomen and marked tenderness, and the condition was attributed to perforated gastric ulcer Yet both temperature and pulse-rate were normal.

Mr. Turner explained that he divided acute abdominal cases into (1) emergencies—i e. those demanding immediate or very early operation and (2) urgencies, those needing attention without delay. The present case he had placed in the second category.

In 24 hours the tenderness had become much less, and the pulse-rate had not risen, while the rigidity had passed off There was a large tumour in the epigastric region and it was resonant Regarding it as a leaking gastric ulcer with a localised abscess, he operated four days after admission he found a tumour the size of a fist in the left lobe of the liver, close to the midline, and a similar lump on the right side near the neck of the gall-bladder A portion removed was gummatous Then the man had admitted he had had syphilis ten years ago, and his Wassermann was found to be strongly positive Injections of novarsenobenzol had already reduced the lump to half its former size

Mr Turner thought the acuteness of the symptoms must have been due to perihepatitis Resonance had often proved a deceptive abdominal sign The lower part of the abdomen was normal

Mr Turner also showed a case of

Fractured Patella Wired in 1889

A woman, aged 60, was admitted for a painful hammer-toe, which was treated surgically A scar about the knee of the opposite side was noticed, and the patient said that Sir Henry House had wired her patella in 1889. The notes of that date showed that three months before her admission she fell and fractured the left patella, and it was put into splints for six weeks Then suddenly it broke again, and Sir Henry House operated under carbolic spray, and kept the limb immobile for seven weeks

A skiagram, said Mr Turner showed the wire still in position. there was perfect bony union with no more arthritis on this side than on the other, and no more than was usual at her age The function of the knee was perfect

Dr C F EAST showed a woman, aged 34, with

Facial Hemiatrophy and Persistent Hiccup

The hemiatrophy had began at 14 years of age, and there were now well-marked changes in all the tissues on the right side of the face and head That side of the tongue was also small and the opening of Stenson s duct could not be seen. The duration of the hiccup was about 13 years it was provoked by emotion and exertion and he regarded it as a form of tic She had considerable periods of freedom from hiccup and the breathing exercises she had been having seemed to have given benefit

Dr L S BURRELL suggested that if the condition was unilateral some good might be done by paralysing the controlling nerve —Dr PARKES WEBER said he considered that if this was a real tic no operation should be attempted especially as improvement was being effected by the breathing exercises —Mr E G SLESINGER disagreed with Dr Weber s implication that because a lesion was functional not organic, it should not be treated by surgery The object of any treatment whether medical or surgical, was to get the patient well in the shortest time

Dr. EAST. in reply said that in a similar case Magnus had found interstitial neuritis of the trigeminal ganglion and of the nerve on the same side of the face.

Mr SLESINGER showed a man. aged 32, with

Arteriovenous Aneurysm

The patient received a bullet wound in the right shoulder in 1918, and in the following year Mr Slesinger saw him because of an arteriovenous aneurysm of the right subclavian. The only complaint he had—and this his wife shared—was that the noise of the aneurysm kept them awake at night. Latterly, however, there had been attacks of pain over the heart and shortness of breath. Skiagrams showed the bullet in the cardiac muscle, probably in front of the intraventricular septum. There was no disability in either arm or hand He told the man he would remove the bullet if it seemed to be moving or interfering with conductivity. Being embedded in a continually contracting organ he thought it would be sure to move

Dr. C WORSTER-DROUGHT brought a man, aged 40. with

Spastic Paresis of One Leg

The complaint was of difficulty in walking owing to weakness of the right leg The right leg was found to be somewhat spastic, with slight general muscular atrophy and weakness. Sensation and coördination were normal Nothing unusual appeared in a skiagram of the spine. The Wassermann reaction in both blood and cerebro-spinal fluid was negative. and the latter fluid appeared normal. There was no history of a previous infecting condition. The illness came on like an ordinary spinal myalgia.

Dr DAVID KRESTIN showed a man, aged 49 who had an

Aneurysm of the Innominate Artery,

which later disappeared

Until seven months before he came under observation in February, 1926, he had been in good health. Then he began to get great pain in the back of the head and the neck. Four months later this improved, but he had a similar pain in the right shoulder and axilla, and the upper part of the anterior chest wall on the right side and the right arm seemed swollen. Six weeks later a swelling the size of a damson appeared just above the right clavicle. At this time he lost his voice and became breathless; he also began to cough. A week before admission to hospital the swelling rapidly increased and became painful. He had gonorrhœa 20 years ago, also what was said to be a soft chancre, which was cauterised. His present inspiratory stridor was well heard The swelling at the lower end of the sternomastoid was the size of a tennis ball and showed expansile pulsation. The second aortic sound was accentuated The man refused any form of treatment and left hospital. Within three months of leaving the swelling entirely disappeared, the general condition improved, and he had since remained at work, without having had any treatment. Nothing could now be felt except an indefinite thickening at the root of the neck, the voice was normal. and both cords moved well. A radiogram of the chest showed dilatation of the ascending arch of the aorta, extending to the innominate artery The Wassermann reaction was strongly positive, and there was no history of trauma.

Dr Krestin suggested that a somewhat acute process had occurred in the wall of the vessel. that blood had exuded into its sheath, so causing a false aneurysm. and that most of the blood had subsequently been absorbed the remainder. after clotting, becoming organised

Dr. V S HODSON said that he had seen a case of aneurysm of the ascending arch of the aorta which seemed likely to burst Following large doses of iodide there was a distinct reduction in the size of the swelling and in a few days all signs of it had disappeared

Mr. ST J D BUXTON showed a case of

Exophthalmos Cured by Ligation of the Carotid

The patient was a woman aged 49, who developed exophthalmos after a street accident. A month after the injury she had diplopia, for which glasses were supplied. Three months later the left eye was proptosed and was slightly pulsating and the conjunctiva was œdematous. With the stethoscope a loud murmur was heard above the orbit, especially over the frontal sinus; this sound ceased when pressure was applied to the common carotid artery. Mr. Buxton operated last February and ligated the left common carotid artery. After this the proptosis gradually subsided, and ocular movements and vision became normal. The patient now had no complaint an opening in the parietes This should be prevented by getting the opening snug round the extruded gut; when established it was best treated by a belt Another late complication was ventral hernia, which no technique could entirely exclude, but the left rectus operation gave better results than the left oblique, and the use of large cups certainly encouraged herniæ Yet another complication was the extension of the cancer to the abdominal wall, owing to a colostomy being made too close to the primary growth If there were not enough loop a transverse colostomy should be done The intestine should not be opened until 48 hours after operation, and with turpentine enemata and paraffin the opening could sometimes be postponed for 7 to 12 days with great advantage The opening should be done with a Paquelin cautery If there was redundant bowel outside it should be trimmed after the fourteenth day under local anæsthesia The daily routine should be a wash-out with 1 to 2 pints of soapy water passed in from a funnel through a rectal tube into the proximal opening, the distal loop should be washed through to the anus if carcinoma were present Patients did very well, they had no sepsis and no irregular actions No cup was needed, the only dressing was a thin piece of cotton-wool, a flat celluloid plate, and a simple corset Patients had to avoid green vegetables, currants, raisins, and sometimes beer and stout, but they had to experiment for themselves and find out what caused diarrhœa

Discussion

Sir C **GORDON-WATSON** said it was time somebody put it on record that colostomy was not the dreadful operation it was supposed to be by the profession and the public If a carcinoma of the rectum was inoperable he always advised colostomy, whatever the condition The patient was more comfortable and healthier after it, and lived longer A proper colostomy properly performed and properly managed was one of the most satisfactory operations of surgery, and after it patients could carry out their work in any walk of life He instanced the driver of a locomotive on the Great Western Railway He believed in a rectus incision close to the umbilicus, and not far from the midline A very important point was to push aside the intercostal nerves, as paralysis of the rectus meant bulging and prolapse He sutured the posterior to the anterior sheath as soon as he had split the muscle, for this limited any bleeding from the deep epigastric vessels or any sepsis that might occur It also prevented the bowel from coming into contact with the muscle where poor adhesion was formed He was a great believer in the glass rod, left in for at least three weeks He thought it a mistake to divide the continuity of the bowel, to suture the skin across through the mesentery, or to suture the bowel to the parietes No bag or cup and in most cases no disc was necessary He had seen two cases of hæmorrhage into the mesentery due to passing the rod under the bowel without mobilising

Mr R P **ROWLANDS** agreed that public and professional fears of the operation were unjustified, it prevented suffering and prolonged many lives He never brought the colon out through the exploratory incision, but made a separate stab incision He preferred the high left inguinal or iliac site When a glass rod was not available, a rubber-covered arterial forceps holding a swab could be used Each suture could be tied to the end of an appendix epiploica to prevent the colon coming further out The deep part of the stab wound was what should be small, rather than the skin orifice Mr Rowlands illustrated some points in his technique by slides.

Mr L **NORBURY** emphasised the need of educating the profession and public, and quoted the case of a man with a colostomy who bicycled from Bedford to London a year after his operation Stout seemed a very bad article of diet, producing diarrhœa, but often beer did not He used a subumbilical incision through the left rectus, as he thought it gave better control than the inguinal site, and that it even gave some hold over the passage of flatus He mentioned some interesting complications he had met retrograde intussusception of the lower end with gangrene, contraction of the opening with formation of a very tight fibrous ring, producing obstruction, coexisting diverticula which might rupture as the loop of bowel was being delivered, and very extensive prolapse of both ends

Mr **SWINFORD EDWARDS** recalled lumbar colostomies he had seen He did not think enough stress had been laid on conferring control after the operation, he had never done an inguinal colostomy again after trying the rectus incision, because the latter did confer a considerable amount of control He wished to stress also the deep silkworm suture through the aponeurosis, through the muscle if need be, and through the mesentery on both sides, so that four peritoneal surfaces were brought into adhesion This prevented a certain amount of prolapse, especially prolapse of the small intestine, and bisected the wound He had always been against cups of all kinds

Mr **TURNER WARWICK** said that the chief factor in preventing prolapse was the posterior rectus sheath; the opening in it should be just large enough to admit the finger He had had no ill-effects from carrying the suture through the bowel wall

The **PRESIDENT** mentioned the difficulty of operating on very fat patients, he had found that the way to deal with them was to take the surface down to the colostomy and not try to bring the colostomy up to the surface He had removed pieces of fat as large as 8 inches in diameter He believed strongly in the rectus incision, which gave an astonishing amount of control Most of his patients only washed out if a normal motion did not occur He never put stitches in the peritoneum, but sewed the anterior rectus sheath to the edge of the bowel

Mr A **LAWRENCE ABEL** said he had been impressed by the good results of Mr Miles's method He regarded a preliminary laparotomy as essential If the bowel were opened transversely there was no hæmorrhage or contraction In the left iliac fossa there were three muscles, each of which contracted, thus giving triple control, also the bowel was more easily brought to the surface there, and so a rod was unnecessary He put in a word for the peritoneal stitch

Mr W S **PERRIN** said that when he had given up the peritoneal suture he had had a case of huge prolapse He had tried both, and could not see much difference between the rectus and iliac incisions

Mr D C L **FITZWILLIAMS** regarded an exploration of the liver as important, the colostomy was then done in the wound already made He used a Paul's tube in obstruction cases, so that lateral wash-outs could be performed He never put stitches through the bowel wall; the appendices epiploicæ were better

Mr E T C **MILLIGAN** mentioned the plight of two men with no fixed abode who were turned out of hospital with colostomies and committed suicide after a few weeks of lodging-house life Any removable carcinoma of the rectum should be removed, whether there were metastases in the liver or not, there was no need for an exploratory operation He used the rectus incision, but had seen herniæ follow it, and the deep epigastric artery might be an embarrassment and source of hæmorrhage Some patients had great difficulty in getting control, and he thought it important to impress on the doctor that the bowels must be kept constipated, and to order wash-outs

Mr **MILES**, in reply, repeated his axiom that it did not matter what method were used provided the colostomy were effective It was a great mistake to delay it in cases of carcinoma, every day of delay was a day to the bad His objections to the rectus method were that it required considerable length of colon and produced a transverse fold within the radial range of the small intestine impulse to kill is attributed by Bjerre to a boundless hate having sprung up in the murderer when he found that he would be compelled to take public responsibility for their conduct, especially was he anxious not to be discredited in the eyes of certain rich old peasant families, and above all in those of his mother under whose complete domination he had always lived The abnormal affinities between such criminals and their mothers is made the subject of very interesting comments

The murderer whose crime is described as an example of "shamming" is a more loathsome person than the others, if possible, he is given as an example of one who strove, even with enthusiasm, to observe in every detail all that he could comprehend of the rules and laws of life and tried to convince himself that he had discharged the duties thus laid upon him, although he lived incestuously with three of his daughters and killed whether in an assault that proved fatal or by deliberate murder, his wife He also committed arson His form of "shamming" —and it is hard to see why he does not fall under the first heading of "self-deception"—seems to be that he justified the pretence to good citizenship because he worked hard on his farm He never thought of burning his property down until economic pressure drove him to do so, while he never thought of killing his wife until it appeared that her evidence might convict him of arson It is hard to credit the narrative, but we are told that the criminal did not believe that the abuse of his daughters was illegal, and justified it on the double grounds of economy and convenience

The book in translation reads easily, and the close investigation and real insight that have gone to its making are apparent Every opportunity that is taken for such psychological studies must supply material for public instruction on the difficult problems associated with crime and its apposite punishment on social grounds Many admirable people, whose kindness of heart all respect would benefit by reading Bjerre's commentary on the charitable proverb "tout comprendre c'est tout pardonner" He finds it a mischievous adage

---

SERUM SICKNESS

Les Accidents Seriques By R J WEISSENBACH and GILBERT DREYFUS Paris Gaston Doin et Cie 1927 Pp 160 Fr 15 40

WITH the increase of the number of diseases treated by serum therapy the importance of a knowledge of the various manifestations of serum sickness is becoming more and more recognised In this small book of 160 pages on serum accidents, the authors have endeavoured to collect and summarise the main papers in the literature, and have added the results of their own experience, together with recently described atypical forms of serum reaction such as paralysis orchitis, and adenitis The work has been divided into four main headings (1) Immediate General Reactions, (2) Delayed General Reactions, (3) Local Reactions, (4) Focal Reactions The acute manifestations, including the sudden deaths that occur immediately after the administration of serum, are described, while a large portion of the book is devoted to delayed reactions, which may occur from the third to the seventeenth day, the majority being observed on the eighth and ninth days after exhibition of the serum, descriptions are given of meningeal reactions manifesting themselves either as sudden shock, or with meningeal symptoms accompanied by changes in the cerebro-spinal fluid In the chapter on pathogenesis the authors consider the sudden cases of death to be due to colloidoclastic shock in persons specially sensitive Similar reports of sudden death due to the injection of peptone have been reported The delayed reactions are held to be anaphylactic in character the mechanism being explained as follows From 10 to 14 days after the first injection there is present in the blood or cells a "toxogénine" or pre-toxin harmless by itself which may persist for a long time At the second injection the antigen unites with the pre-toxin, forming an apotoxin, the toxicity of which is augmented by the complement in the blood and which forms the anaphylactic poison The section on treatment deals with (1) prophylaxis or preventive treatment and (2) curative treatment The lessened danger of serum disease when "refined" or concentrated material is used is emphasised and the lines of treatment are standardised

A bibliography of 86 names is appended and the references are all to French authors, with two exceptions, these being to an English and an American writer respectively While much has been done by French workers on the subject of serum disease there is no justification for the omission in the bibliography of the important contributions emanating from other countries

ULTRA-VIOLET THERAPY.

Clinical Application of Sunlight and Artificial Radiation Including their Physiological and Experimental Aspects with Special Reference to Tuberculosis By EDGAR MAYER, M D London: Baillière, Tindall and Cox 1926 Pp 468 45s

THE scope of this book is very wide Many subjects other than light therapy are considered, all of them bearing upon this form of treatment in one way or another The book has in all 468 pages, of these only 39 are devoted to the Clinical Application of Solar and Aerotherapy, and 73 to Clinical Studies with Artificial Light and the technique pertaining to it The remaining parts are given up to physics, the action of light on animal and plant life, the physiological action of light and the skin as an organ with special reference to its reactions to light. The small amount of space given to the clinical side may disappoint the practical worker who has been attracted by the title, but the rest of the matter is well worth his attention The author writes to some extent from his own experience in the treatment of tuberculosis at Saranac Lake, New York State, and his conclusions are that in treating this disease, reliance should primarily be placed upon rest, diet, and hygienic outdoor existence For the artificial aids to sunlight treatment the author has a good word he insists upon the necessity of individual attention upon each case, for he has found that some conditions not responding to sunlight and open air alone may require ultra-violet and heat radiation, X ray exposures, or indeed some combinations of these forms of therapy He includes in this book a chapter on the X Ray Treatment of Tuberculosis

The preparation of the book has evidently involved much labour · no less than 100 pages are devoted to a bibliography and index

---

ADOLF KUSSMAUL

The Life and Time of Adolf Kussmaul By THEODORE H BAST, Ph D, Associate Professor of Anatomy, University of Wisconsin Medical School With a foreword by WILLIAM SNOW MILLER, M D D Sc, Emeritus Professor of Anatomy, University of Wisconsin Medical School New York Paul B Hoeber 1926. Pp 131 $1 50

THIS book is an expanded version of a paper read by its author before the Wisconsin University Medical History Society Kussmaul is, perhaps, best known in this country as being the first to practise œsophagoscopy and gastroscopy, the instrument used being the endoscope of Desormeaux This was in 1868 although Cruise, of Dublin, had suggested the use of the instrument for examining the stomach in 1865 Kussmaul was also the first to describe periarteritis nodosa progressive bulbar paralysis, and diabetic coma with acetonæmia Dr Bast gives many particulars of Kussmaul's early life He was born in 1822 at Graben near Karlsruhe his father being also a medical man Adolf Kussmaul had a sense of humour his name which, Anglicised means "Kissing mouth" caused him some embarrassment, The PRESIDENT congratulated Mr Buxton on the brilliant result The safety or otherwise of ligature of the carotids depended greatly on the condition of the arterial wall In young people there need be no anxiety, but in old persons it was a serious matter —Mr SLESINGER remarked on the uncertainty of the ultimate prognosis in these cases

Mr BUXTON replied that Mr Slesinger's remarks applied to exophthalmos following a bullet wound, rather than to exophthalmos resulting from a small fracture of the base of the skull

Dr HODSON showed a case of

Amœbic Hepatic Abscess

The patient was a man, aged 39, who, in June, 1926, had dysentery in India and was successfully treated with emetine He returned to England late in the year, felt ill in January last, and slowly got worse When seen by Dr Hodson on April 1st he had the typical condition of amœbic abscess, and the right side of the chest showed limited movement and a slight prominence over the liver Hepatic dullness began in front of the fourth intercostal space in the nipple line Skiagraphy showed a definite upward enlargement of the right lobe of the liver, with fixation of the diaphragm He prescribed for the patient gr 1 of emetine daily for three days, and told him to return in a week When he did so he said riding in an omnibus no longer caused him pain, and that he was able to do his work in increasing comfort A few more days of emetine treatment, of similar dosage, were followed by diminution of the protuberance of the right lobe and some diaphragm movement Some days later he only complained of a feeling of tightness over the liver Nine days' treatment brought about complete recovery

Dr Hodson said the case, like a number of others, showed that there was now no need to deal with this condition surgically This condition was not strictly speaking an abscess, but was more comparable to a gumma He believed that too large doses were given for this condition The only cases of mixed infection he had seen were those in which contamination of the wound had followed aspiration He had had five previous cases of the kind in which the results had been similar

Other Cases

Dr PARKES WEBER *showed a case of Pituitary Tumour*.

The patient, a man aged 47, had a pale cachectic appearance, with moderate anæmia, chronic headache, hemianopia (bilateral), and apparently an enlargement of the pituitary fossa The Wassermann reaction was negative His hair was scanty, he had none in the axillæ He was the father of four healthy living children During the last year he had been sexually impotent Some improvement had followed, brought about, Dr Weber suggested, by leakage of a pituitary cyst into the cerebro-spinal fluid

Dr WEBER also exhibited a man, aged 36, whose complaint was that of general weakness, and whose condition he diagnosed as abdominal lymphogranulomatosis maligna There was, he said, a very high degree of eosinophilia In the abdomen, to the left of the umbilicus, was a deep, hard, immovable swelling, but there was no sign of hydatid disease Apparently the spleen was enlarged The fæces contained occult blood

Mr C LAMBRINUDI showed a girl, aged 16, and asked for help in the diagnosis of her condition

At 2½ years of age she fell down stairs, and afterwards developed diarrhœa and vomiting, and pain in the back and neck Lumbar puncture was negative Her gait was very awkward, the knees and hips were somewhat flexed, and the back markedly lordosed, the knee-jerks were absent The extensors of the knees, the psoas, and adductors of the thighs were paralysed on both sides, and there was some contracture of knees and hips Both glutei maximi were much enlarged

He asked whether this was anterior poliomyelitis, or an unusual case of pseudohypertrophic muscular dystrophy *He believed it to be the latter*

Dr WEBER thought the patient had had infantile paralysis, though she might now be developing a primary muscular dystrophy It was suggested that underlying these conditions there was a weakness in the central nervous system

THE PSYCHOLOGY OF MURDER

A Study in Criminal Psychology By ANDREAS BJERRE Translated from the Swedish by E. CLASSEN London Longmans, Green and Co 1927 Pp 164 9*s*

THIS book consists of three essays and an explanatory foreword, and constitutes, we are told, the first of a series of contributions to the subject, but as the author, who was professor of criminal law at the University of Dorpat, died young some 15 months ago, the sequels must be projected from other pens Mr Birger Ekeberg formerly Minister of Justice in Sweden, in a brief preface prepares us for the close analysis of the psychic life of criminals which Bjerre is able to supply, and testifies to his devotion throughout many years of his life to the study of Swedish prisoners in order by constant personal association to solve the riddles in their dark lives And certainly the three careers are dark enough which Bjerre supplies in illustration of the general propositions which he thinks to be warranted by his experience

In Bjerre's view, detailed investigation of the lives of particular offenders is much required, existing estimates of the character of homicidal criminals being too much based upon predetermined theses He recognises that some classification, according to common characteristics, must be the essence of scientific research, but finds that many widely accepted generalisations with regard to murderers are incorrect, because it has not been sufficiently recognised that there is with them a real inability to conform to ordinary type, so that deductions from their actions, based upon deductions from the actions of the mass, are likely to be faulty His contribution to classification takes the shape of a great generalisation—namely, that *weakness* (italicised by Bjerre) on the part of the criminal lies at the root of most murder crimes He does not profess to be satisfied with the theory as being complete, it formed in his mind against his will, and as a result of deeper intercourse with criminals he became fortified in the view And in what he means by *weakness* lies the originality of his ideas

The defect of *weakness* he divides into three classes as there is produced by it (1) "self-deception," (2) "anguished fear," and (3) "shamming", and the conduct of the particular criminals whose offences he details illustrates the three defects

The first, a hanger-on of brothels from the age of 15, requiring money to supplement his wages and his earnings as a *souteneur*, embezzled and departed with an associate, who had influenced him with stories of the wealth of great cities, on a rambling tour through Europe They remained at large for some months, spending the results of the crime until they were swindled by a theatrical adventurer, apparently a sexual pervert, and found themselves back in Sweden penniless They then murdered a postman on an elaborate but clumsy plan and were arrested The sentence of imprisonment for life gave Bjerre the opportunity of exhaustive analysis, and the reasons for classification of the case as typical of self-deception emerge The murderer had persuaded himself that the victim, whom it was only intended to stun, must carry at least 40,000 crowns, which society owed to his assailants, whose difficult position as penniless outlaws justified their action

The career of the second murderer explains what the author means by "anguished fear " Among these criminals a consciousness is engendered that something has been radically wrong in their lives from the beginning, leading them to a consciousness that definite individual effort from them will be useless The desire to conceal from the public actions which are esteemed reprehensible becomes coupled with a horror of all responsibility The murderer in whom *weakness* took this shape first attempted to poison his fiancée who was enciente by him, and later murdered her immediately after intercourse The

MALFORMATIONS OF THE ALIMENTARY WALL

DIVERTICULA of the colon, to which a large space is devoted this week both in text and illustration, have been known in the dead-house for a century or more, but it is only within recent years that conviction of their frequency in late middle life is being brought home to the clinician, and this, as Sir BERKELEY MOYNIHAN points out, is the result of the increasing frequency of abdominal operations and of the aptitude of radiologists Among 1000 consecutive patients under the care of Dr E I SPRIGGS, in whom an X ray examination of the alimentary canal was made by Mr O. A MARXER, 10 per cent were found to have some stage of diverticulosis at an average age of 58 years While the yielding of the intestinal wall is an accepted fact, it is not yet agreed what is the cause of the yielding Some cases may be con- emital in origin, and in others the yielding is ascribed o long-continued increased pressure from within Addressing the State Medical Association of Texas Dr W S BAINBRIDGE recently stated his personal elief [1] that a large proportion of intestinal diverticula ave their origin in the mechanical factors of con- ipation But apparently Dr SPRIGGS's cases were not ore constipated than the controls, although there as frequent association with septic foci in other rts of the body, particularly the teeth, and with rly arthritis of the spine One-half of the affected rsons in this series suffered no inconvenience from e diverticular state of the bowel, and it is the rticular merit of Mr MARXER's work that he has monstrated by convincing X ray films the characterics of a prediverticular state which precedes for longer or shorter time the condition of established verticulitis His pictures show beyond contradiction at diverticula may be quiescent for years, serious mptoms only arising when they become mechanically ocked, it is delay in the pouch rather than in e bowel which is harmful Identification of the ease at an early stage has completely altered the tlook for these patients, which cannot be judged om the end-results of the operating and post-mortem oms such as those scheduled in our columns [2] by L R FIFIELD In the great majority of cases dical treatment will hold the symptoms in check, long as the alimentary canal is kept clean and ricated with paraffin under occasional review by barium enema the severer complications can be tponed and even avoided

Whether or not diverticulosis is of congenital origin f considerable interest in view of recent laboratory k on malformations of the alimentary mucosa would appear that errors or variations from the mal are commoner than used to be thought, and A L TAYLOR, working in Prof. STEWART's laboratory at Leeds, brings this out very clearly in a comprehensive account [3] of the epithelial heterotopias of the alimentary tract He describes in all 81 instances where epithelial structures properly belonging to one part of the alimentary tract have been found in another place, and this number could no doubt have been considerably increased if he had searched more thoroughly for the gastric glands which were found in the œsophagus at the level of the cricoid cartilage in as many as 70 per cent of bodies by SCHRIDDE Indeed, it seems likely that the complete examination of alimentary canals in serial microscopical sections might yield so many "abnormalities" that some of them would have to be reckoned at least as "normal" as the conventional descriptions in the text-books Limiting himself, however, to those of which some suggestion was apparent on naked-eye examination and those found in sections made for other purposes, he has found plenty of cases which he classifies into a most interesting catalogue Gastric mucous membrane is found in the œsophagus, duodenum, ileum (rarely), in Meckel's diverticulum, and in umbilical polypi Intestinal epithelium occurs in the stomach with surprising frequency in a series of 158 stomachs removed by operation (and it is only such material that can be examined properly for these details) it was found no fewer than 36 times —i e, in 23 per cent of cases In one case, Brunner's duodenal glands were identified in the gastric mucosa Similar misplacements of structures which normally lie deep to the muscularis mucosæ were also found the curious combination of glandular tissue and muscle known as "adenomyoma," occurred in the stomach and duodenum, and aberrant pancreas was found widely scattered in stomach, small intestine, and in Meckel's diverticulum Misplacements or malformations similar to this congenital series may also occasionally arise, secondarily, in sequence to destructive inflammatory and ulcerative lesions The whole account is fully documented and forms a valuable survey of a bypath in morbid anatomy In conjunction with it, Dr G W NICHOLSON's thoughtful papers in *Guy's Hospital Reports* in 1921–24 might be read again with advantage by pathologists and, we venture to suggest, by comparative anatomists as well

Of the many topics which arise out of these considerations, we can mention only two It is clear, in the first place, that there is no evidence at all that tumours, either innocent or malignant, have any special tendency to arise in malformations of the alimentary tract Adenomyoma is in some respects tumourous in character, but it has no particular propensity to develop further along these lines The more, in fact, that we know of anatomical "embryonic residues," the less likely does COHNHEIM's suggestion become The second consideration is the clinical importance of these malformations Most of them have none But Dr TAYLOR describes very striking cases where gastric mucous membrane in the ileum was associated with fatal ulceration, where misplaced Brunner's glands led to a duodenal ulcer in the stomach, and where gastric glands in Meckel's diverticulum give rise to repeated small hæmorrhages from the bowel so characteristic as to be susceptible of diagnosis Adenomyomas of the stomach fairly often give rise to serious dyspepsia their nature should be recognised for they are liable to be mistaken at operation for carcinoma and an extensive gastrectomy done instead of the local excision which is all that is needed

[3] Jour Path Bact, 1927, xxx, 415.

and when he was assisting Naegele at Heidelberg the worthy professor advised him to change it. Kussmaul declined because, he said, his family was descended from the noted physician to the Emperor Julian, Oribasius, who after Julian's death was banished from court and settled with some Goths on the Danube. Here his name was translated into Kussmaul from Os oris, a mouth, and Basium, a kiss. Dr Bast has supplied a simply written and sufficiently full record of one who benefited his fellows in many ways by his learning, and his little book will be valued by medical historians.

JOURNALS

Veterinary Journal.—The April issue is devoted entirely to the subject of clean milk, and contains interesting and authoritative articles on the subject written by members of the veterinary profession, medical officers of health, and others who have practical acquaintance of the relation of clean milk to the health of the general public. An editorial suggestion is made that the best method of ensuring that milk shall reach the public free from injurious matter is by cooperation, for inspection purposes, of medical officers of health and veterinary and sanitary officers, each of whom would find plenty to do in his own sphere without overlapping.

Mr Gofton, the chief veterinary inspector to the City of Edinburgh, draws attention to the mental chaos of the milk producer and dealer in respect of clean milk, until 1922, when the Milk and Dairies Amendment Act was made law, and milk was officially designated, "The Milk (Special Designations) Order" bringing the necessity of recognising the hygienic quality of milk before the Public Health Authorities, and the traders and consumers. During the past year the Milk and Dairies Act has been strengthened, and though there is room for further amendment, the general public, as a body, have learnt to object strongly to a sediment of cow manure at the bottom of the glass of milk purchased as a beverage. If the public can be brought to see that it is readily possible to produce clean milk, the farmer and dairyman will soon take the necessary trouble to prevent its contamination. The lectures of the National Milk Publicity Council in England, and the Scottish Milk and Health Association in Scotland, both of which aim at increasing the consumption of milk and improving its hygienic quality, are already having their effect, and such institutions as the National Institute for Dairy Research at Reading, and similar schools where instruction is given to teachers and dairy farmers, are producing a sanely critical frame of mind in purchasers.

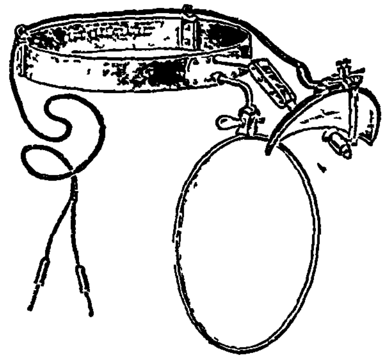
Colonel F E Fremantle, in a practical contribution, draws attention to the fact that the average consumption of milk per person in Great Britain is less than a quarter of that in the U S A, that tubercle bacilli are still to be found in samples of milk taken in our large towns, and that some 3000 British children die annually from drinking tuberculous milk, a preventable mortality which he describes as "constituting a disgrace of the nineteenth century which must be wiped out in the twentieth." For this elimination process he emphasises the great help which human medicine can obtain from collaboration with veterinary medicine. The same alliance for practical purposes is advocated by Mr E J Bundred of Blackburn, and Mr Robinson of the Harper Adams Agricultural College. The problems of a clean London milk supply are dealt with by Dr C W Hutt and Dr J B Howell, the medical officers respectively for the Boroughs of Holborn and Hammersmith, and Dr E G Gibbs-Smith, medical officer of health for Teddington, has written an especially practical and pithy article on the dangers of the present bottling system of milk distribution. After pointing out the disadvantages of the present shape of bottle and the faulty method of capping which is used by many vendors, he makes an excellent suggestion (which some of us may still live to see adopted) that a cardboard container (as in the case of cream) should be utilised, which would be used once only and then destroyed. He gives as his particular reason for this, that it would eliminate the danger of infection from imperfectly sterilised bottles, and instances a dairy which he recently visited where the cleansing was done by hand, and where, after the bottles were supposed to be clean, the bottom edge of the insides still contained quantities of congealed milk. Dr Gibbs-Smith also draws special attention to the advantages of a cap which fits completely over the top of the bottle and opens outwards, and Prof F Hobday, in an article embodying the treatment of milk in Sweden, particularly draws attention to the fact that this suggested system of capping is the one almost exclusively used in that country and in Denmark. The treatment of milk in these two countries, which may be considered to have given a lead to all other countries, is fully dealt within two articles by Profs Morkeberg and Hobday, and attention is drawn to the hygienic quality of milk which is drawn direct from the cow into sterile containers by the use of the Alfa-Laval Milking Machine, which is almost universally employed in Sweden and is now being used extensively in Great Britain. There are interesting discussions on the value of pasteurisation by Mr Tustin, technical adviser of the United Dairies Company, and Mr Edward Somer, one of the veterinary inspectors for the City of Birmingham, the latter holding that "pasteurisation is only a palliative measure, and does not help towards the production of clean milk . . helps to shield the dirty farmer and does not encourage cleaner methods of production."—Other valuable articles, contributed by Mr G Mayall, Mr W Forbes, and Dr Nathan Raw, help to make this special clean milk number of interest to those engaged in promoting the public health.

Dr G E Wyeth's "Surgery of Neoplastic Diseases by Electrothermic Methods," reviewed in this column last week, is published in this country by Mr Humphrey Milford at the Oxford University Press, price 38s.

New Inventions.

A MODIFIED FACE SHIELD

I have had made for me a modification of Killian's face shield with fibre head band in which celluloid is used instead of glass. The Killian's shield is a very useful appliance in an ophthalmic out-patient clinic where it is necessary for the surgeon to approach his face close to that of the patient. In a big out-patients' department it is almost essential, for in addition to acting as a breath shield and allowing surgeon and patient to talk freely without unpleasantness, it protects the surgeon from infections of the throat and nose which he is otherwise almost certain to contract should he be obliged to face a large number of cases daily. The advantage of the celluloid is in its lightness. The glass shield is more transparent, but it has the disadvantage of fogging when breathed on, it is also liable to give rise to headache when worn for a long time owing to its weight. This celluloid shield has also been adapted to the Clar head mirror (half mirror) as shown in the illustration. It has similar advantages to the above when used for work requiring a head light.



Messrs Down Bros, Ltd, 21 and 23, St Thomas's-street, London, S E 1, are the manufacturers.

Madras R E Wright, Lt Col, I M S

suspended matter, contains few microbes of any kind. and although hard the hardness is for the most part of a kind which is dissipated by boiling—SIR ALEXANDER HOUSTON does not himself believe that hard water is unhealthy. Some of the wells are situated so far afield as on Westerham Hill near the Pilgrims Way, and at Sundridge near the source of the Darent; at Eynsford, a little lower down the Darent Valley, the latest boring has just been completed The abundance of "indifferent" water in the county is contrasted by the Director with the paucity of mineral springs, of which practically the only example is the once famous well at Streatham, the water of which was used for long as an antacid tonic aperient

The Metropolitan Water Board, with SIR ALEXANDER HOUSTON in charge of water examination, stands as a champion of the utmost refinement in preventing pollution of a water designed for human consumption It is foolish the Director has said on several occasions, to allow preventable pollutions to reach a supply antecedent to purification, during and still more after purification it is "simply madness" The moral to be drawn is that cross-connexions of water-supplies should be avoided. The circumstances of an outbreak of illness which occurred at Poplar in July last, and are now the subject of a special report,[1] afford a good illustration of the cogency of this belief The outbreak, which at first was thought to be due to the ingestion of ice-cream was soon seen to be highly significant of a localised water-borne infection, owing to its sudden outburst, its brief duration, its incidence on all ages and mainly on women and children, and its selective distribution of cases in the vicinity of the gasworks The clinical symptoms were remarkably similar, diarrhœa being constant and severe, with fever ranging from 100° to 104° F, and nervous symptoms manifested by convulsions or fits not wholly confined to young children The symptoms, alarming enough at the outset, subsided for the most part in 24 hours, although two cases ended fatally After the attack labial herpes commonly appeared, often associated with buccal ulcers The character of the outbreak closely resembled one which occurred near Mansfield in 1915 due to pollution by sewage of a water main, when there were 1700 cases without a death, and Dr J C G LEDINGHAM isolated the Flexner Y type of dysentery bacillus In the Poplar outbreak however, no microbes were isolated which could possibly be concerned as causative agents, although this does not exclude the possibility of dysentery, for, as Dr W M SCOTT points out, the bacilli may very easily be missed The most probable source of contamination appears to have been the reflux of polluted water from the local gasworks into a main of the Metropolitan Water Board and the report contains an elaborate plan of the piping which made this pollution possible The serious aspect of such an outbreak is illustrated by the experience of Hanover last autumn when a fulminating attack of typhoid was preceded for a fortnight by a "water-sickness," due apparently to the ordinary bacteria of sewage when 20–30 000 persons suffered from acute gastric and intestinal catarrh Early last month the town of Elgin had a somewhat similar visitation on a small scale many families being attacked by violent vomiting generally accompanied by diarrhœa, to which it is reported the medical officer of health himself fell a victim The outbreak was there traced to a contaminated water supply, having coincided with the commencement of the cleaning of the main pipe which brings to Elgin the supply of water from Blackhills reservoir In this case the illness had no serious sequel. The Public Health Council of New York State recently collected evidence [2] of 38 outbreaks of typhoid fever which have occurred since 1903 within the State Department of Health. all of them definitely traced to cross-connexions between public water-supply and polluted private auxiliary supplies Leakage of check-valves may result, the journal remarks, in polluted water entering distribution systems of potable water and so render void all the costly precautions Cross-connexions of water-supplies have now been prohibited in the entire State of New York excepting New York City. The serious outbreak of typhoid reported this week from Gravesend is not attributed to pollution of the water-supply

THE SITE OF THE UNIVERSITY OF LONDON

IT was announced last week that the University of London had been placed in a position to buy the Bloomsbury site It enters thereby upon a stage of development where not only will it be able to discharge its great work better, but where it can realise in a fuller manner the noble promise of that work. so taking up the proud position implied by its title The well-being and the progress of the University of London are necessarily dear to the imagination of the medical profession, which knows well how much it has owed and still owes to the famous medical faculty of the University, but the exigencies of the medical curriculum have been responsible for many vexatious dissensions in the past The purchase of the Bloomsbury site will have no sequel of that unfortunate sort: all the University must be benefited thereby The money has been obtained largely through the bounty of the Rockefeller Foundation

The University now possesses some eight and a half acres excluding roads, in a most favourable place It is the site which was bought by the Government for the University some eight years ago, but which was reconveyed to the vendor, the Duke of Bedford owing to the University at the time finding certain conditions impossible to comply with The chief among those conditions was the one which required from King's College surrender of its present site and of this there is no longer any question Of the eight and a half acres at the disposal of the University one small parcel has already been allotted for the erection of the central offices which will be transferred there from South Kensington, though the examination rooms at the Imperial Institute may still remain at the disposal of the University. The other most immediate demands upon the site would seem to be recognised by common accord to be as follows—perhaps in order of urgency There must be a senate house a central library a club for teachers, a students' union and headquarters for an officers' training corps Large sums of money will be required before such a central framework of a modern university can be erected and it is perhaps just as well that for this material reason there can be no premature rushing into bricks and mortar Secure in the knowledge that the site is their own the authorities can proceed to plan a university centre worthy of the capital of the Empire, and can plan it with an eye to proper development as much as to present needs

PROBLEMS OF PELVIC INFLAMMATION

The recent Congress of Obstetrics and Gynæcology held at Manchester called forth various expressions of opinion on the treatment of inflammatory conditions of the uterine adnexa, and the different points of view are worth recalling Mr **Aleck Bourne**, who opened the discussion of this subject, confined his remarks to the treatment of acute gonococcal salpingitis, holding the opinion that in severe cases operation should be done in the acute stage, the tubes being slit and drained through the abdominal wall Prof **Beckwith Whitehouse** spoke of tubal inflammation in general, for which he adopts more conservative methods It is his practice, he said, to interfere surgically only when there is an extension of infection from the pelvis to the general peritoneal cavity or where there are indications of the presence of pus When interference is required his preference is for the vaginal route, and his object is to create as little disturbance as possible during the acute stage, fertility is least impaired when the operations performed are of the simplest kind With expectant methods, he remarked, "there is a strong probability that surgical treatment will be required at a later date, but it will be undertaken at a time when such intervention is safe and with a correspondingly low mortality (2 5 per cent) It is only in a comparatively small proportion of cases that radical measures, such as hysterectomy, will be necessary after such conservative surgical treatment" At the Birmingham General Hospital between 1911 and 1923, he stated, there were 137 hysterectomies among 387 operations performed for inflammatory pelvic disease, the mortality was 5 per cent No doubt the operation was done in the belief that the infected uterus remains a menace to the patient even if the tubes are removed There is very little reason to think, however, that the body of the uterus continues to be a potent source of infection, though there is plenty of evidence that the cervix harbours germs indefinitely Consequently, it seems that if anything at all is done to the uterus the cervix should be removed, as was advocated in the discussion by Dr S J **Cameron** In gonococcal cases, generally speaking, hysterectomy appears to be quite unnecessary, but it is logical to excise the interstitial portion of the tube with the cornu of the uterus, and this operation has many advocates

Prof **Blair Bell** spoke on the conservation of ovarian function in the surgical treatment of salpingitis, and agreed that the ovary should be preserved in its normal position wherever possible Where this cannot be done, he recommended that the ovary should be grafted elsewhere, as, for instance, to the uterine cornu or the rectus muscle Whilst all surgeons would agree that the ovary must be kept as long as the uterus is also present the short life and activity of a grafted ovary makes this procedure of doubtful utility, and sometimes a grafted ovary has had to be removed later because of trouble which has developed in or around it Several speakers were concerned with the fate of the ovaries after hysterectomy Prof **Archibald Donald**, in particular, held the view that they should always be removed with the uterus, and that a woman who has no uterus is just as well without her ovaries There is very little doubt that the ovaries atrophy rapidly after hysterectomy, and there is no definite evidence that the menopausal symptoms following this operation are any less distressing if they are preserved In this matter gynæcologists have undoubtedly been swayed by public opinion, and it has become the custom to preserve ovaries—even those in which there is a suspicion of infection—though it is very doubtful if the patient is any the better for this kind of conservatism

The end-results of salpingostomy performed for chronic tubal inflammation were discussed at the Congress by Dr **Bethel Solomons**, who recommended that during the abdominal operation the tubes should be inflated from the cervix to demonstrate the site of obstruction He detailed the operations for the cure of tubal obstructions, and reported that 32 patients subsequently conceived out of a series of 72 who were treated by salpingostomy Although hardly germane to the subject of discussion, it is of great interest to see that so many patients have become fertile after this operation, and this result lends weight to the plea for conservative measures in the acute stages Further support was given to this view by Prof. A H **Curtis**, of Chicago, who advocated expectant treatment in gonococcal salpingitis and said that he operated only for the sequelæ of the disease From the course of the discussion it was clear that the old principle of leaving acute gonococcal salpingitis alone is adhered to by the majority of gynæcologists The mortality of cases thus left is almost nil, many patients recover so completely that they conceive afterwards, whilst if recurrent attacks of peritonitis occur, operations can be done with greater safety at a later stage, when parts can be preserved which might well have been condemned to removal if seen when the inflammation was at its height Another point which emerged from the discussion is the importance of distinguishing gonococcal from streptococcal infection, which may be very difficult where there has not been a recent pregnancy

◆

WATER, PURE AND POLLUTED

The water drawn from the deep chalk wells of Kent is of unique purity and nearly inexhaustible quantity, and these wells, as we learn from Sir **Alexander Houston**'s latest report,[1] contribute about one-tenth of the total drinking water-supply of London, an amount which would suffice at 35 gallons per head per day for the supply of a town the size of Manchester Sir **Alexander Houston** takes the reader in imagination a delightful tour of the water-courses of the county, beginning in Deptford with the little known Ravensbourne, where the first pump was worked by a waterwheel designed by **John Smeaton** and steam-engines by **Boulton** and **Watt** were in action up to 1925 Unfiltered water was used until 1844 when the first filter bed was constructed, and a few years later an open reservoir was made which still remains as an ornamental pond in the district engineer's garden Then came the epoch of deep well boring which has again made it possible to deliver the water direct to the consumer without artificial treatment of any sort The only reproach which can now be brought against the Kentish wells is that their pumping operations have reduced the flow of the once abundant surface streams in which trout could be captured within living memory There would still seem to be plenty of water available in the vast bed of chalk which underlies the country and is only thinly covered by pervious strata where it does not reach the surface, only the new red sandstone is a possible competitor as a water-bearing formation The depth of the source ensures a cool supply on the sultriest days of summer, and the water is devoid of colour, is completely free from analysis it may be considered that in 73 per cent. of cases submitted previously to operation symptoms persisted, and in 82 per cent. there existed definite evidence of changes in the prostate or the seminal vesicles or in both on rectal examination. As regards the contained secretions only 11 patients (or 18 per cent.) had normal fluid, while 82 per cent. gave evidence of pus in the expressed secretions. The lesson to be derived from these observations is that failure on the part of vasostomy to relieve symptoms must to a great extent be attributed to the persistence of urethral lesions that are untouched by this operation; but even apart from such associated lesions, vasostomy would appear to have very little effect on chronic infections of the vesicle and prostate. Indeed when the anatomy of these structures is recalled it would be surprising if a single washing out of the vesicle with disinfectant were enough to effect a cure. The pelvis of the kidney is a cavity of comparatively simple structure compared with the lumen of the vesicle, yet a single renal lavage seldom effects a cure in a case of pyelitis. How slender is the hope, therefore, of stamping out a chronic infection of the vesicle by a single vasostomy. Dr. Kretschmer's analysis suggests that little can be expected of it.

THE SURGICAL TREATMENT OF PULMONARY TUBERCULOSIS

IT was in this country, over a hundred years ago that the first proposal to treat pulmonary tubercle by artificial pneumothorax was made by James Carson; yet the method was not practised here until long after it had become established abroad, and to de Cerenville, of Lausanne, belongs the credit of having made the first attempts at collapsing the lung by surgical means. His work had but little influence at the time, but a little later Quincke and Carl Spengler—independently of one another—had the same idea, and it is owing to their influence that thoracic surgery has made such strides in Germany. France, like other countries, has been slow in accepting this advance in treatment; even to-day there seems to be a persistent inertia and lack of faith; and it is therefore particularly interesting to read the contribution which L. Berard and F. Dumarest make to the April number of the *Revue de Phtisiologie*. For a long time these authors have been ardent upholders of modern thoracic surgery, and their results add confirmation to the mass of evidence—mainly German and Scandinavian—in favour of surgical intervention in selected cases of pulmonary tuberculosis. The successful results of thoracoplasty are even bringing about a reconsideration of the rule that this operation is unjustifiable if artificial pneumothorax can be done. Berard and Dumarest state that whilst artificial pneumothorax gives the best results at the beginning of treatment, its complications and the fact that the lung expands again make it ultimately less successful than thoracoplasty, where the case is chronic and where there is moderate resistance and capacity for the formation of fibrous tissue. Thoracoplasty is applicable only to chronic cases, whereas artificial pneumothorax may be used in acute cases as well, and when it is successful is preferable to a complete thoracoplasty. Berard and Dumarest consider, moreover, that sometimes a partial pneumothorax with hemidiaphragmatic paralysis has advantages over a complete pneumothorax. They are unquestionably sound in upholding the modern tendency to limit rib resection to the minimum compatible with efficient collapse of the affected part and to supplement this resection by phrenic evulsion. The best collapse of the apex is by partial thoracoplasty involving the first seven ribs; efficient collapse of the upper lobe and of the upper part of the lower lobe can be secured by thoracoplasty of the upper eight ribs and hemidiaphragmatic paralysis. The decision to do a thoracoplasty, as they point out, must not be made on a symptom or on a lesion, but on the considered merits of the individual case, and for this reason they urge that the cases should be studied and operated on in sanatoriums. The indications which they give are long standing, fibrotic and only slightly active disease with adherent pleura and a good general state of health, as well as conditions in which there is marked displacement of the mediastinum, or hæmorrhage. Thoracoplasty is also indicated for cases in which extensive effusion has developed after treatment by artificial pneumothorax, for tuberculous empyemata with mixed infection, and for bronchial fistula. In these last groups, however, the risks of operation are considerably increased. In all cases for which thoracoplasty is proposed the lesion in the opposite lung must be anatomically unimportant, fibrotic in character, and absolutely inactive. There are no special new points in the technique of Berard and Dumarest, but their observations on two vexed questions are specially interesting. At first, operating in one stage, their mortality was 33 per cent.; later, operating in two stages, it was reduced to 5 per cent. They use either local or general (ethyl chloride) anæsthesia, with a "certain preference" for the latter. Their statistics for 91 cases show "cured" 28 per cent., improved 22 per cent., and an immediate mortality of 18 per cent. Sauerbruch's statistics, which they quote, show 'cured' 42.2 per cent., improved 17.5 per cent., and an immediate mortality of 13.3 per cent. These figures are for 646 cases operated on before June, 1925. In the next 18 months 160 cases were treated with an immediate mortality of 5.5 per cent. To sum up, their paper shows once more how much can be done in selected cases by thoracoplasty and by phrenic evulsion to ameliorate the condition or arrest the course of pulmonary tubercle after all other means have been tried and when without surgical assistance the patient is doomed to a decline. Of those whose lives can thus be saved from one-third to one-half are returned to health fit to work, whilst an even larger proportion, being freed from infection, can enter again into home life without danger to those around them.

DEFINITION OF BLINDNESS

THE Blind Persons Act of 1920 has now been in operation for more than six years and, giving as it does certain monetary privileges to the blind, necessitates a definition of that term. The Act itself merely contains the somewhat vague definition, 'too blind to perform work for which eyesight is essential.' As Dr. A. H. Thompson points out in his Analysis of the Causes of Blindness on p. 1075 of our present issue, only a small proportion of those who need to be educated as blind have completely lost the power of perceiving light or recognising the movement of bright objects. He emphasises the fact that the acuity of central vision is not alone a sufficient criterion of blindness in the economic sense. There are, for instance, persons who can read the smallest type and yet have to be led about the streets owing to curtailment of their field of vision. The Ministry of Health is taking these factors into consideration. Last year[1] Circular No. 681 intimated that any person whose visual acuity with correcting glasses is greater than 6/60 cannot be considered blind within the meaning of the Act unless the defect of eyesight includes such special conditions as a great contraction of the field of vision. Another circular (No. 780) just issued repeats this intimation and states that on the whole the suggested criteria have afforded trustworthy guidance in determining whether a person is too blind to perform work for which eyesight is essential. It should be understood that the limit of visual acuity (6/60) is not to be regarded as a hard-and-fast line. Contraction of the visual field, which may be due to glaucoma, to retinitis pigmentosa, to partial optic atrophy, or other rarer conditions, must also be taken into account. Further, 'marked nystagmus' is mentioned for the first time as a disabling condition, and lest any other disabling

Annotations.

“ Ne quid nimis ”

THE ROYAL SOCIETY'S CONVERSAZIONE

ON the evening of May 11th the Royal Society held the first of its half-yearly conversaziones at Burlington House. As is usual at these gatherings a number of exhibits were on view, and two demonstrations were given, the first illustrating the courtship of birds, and the second, by Sir Almroth Wright, F.R.S., dealing with the phenomena of intertraction. Sir Almroth Wright began by describing some observations, made in wounds, which had led up to experiments in vitro on the behaviour of saline solutions and serum in juxtaposition. Having displayed the intertraction between these media he ended his demonstration by showing the traction effects of hypertonic salt solution in a model section of a wound. Another exhibit, dealing (from a different aspect) with the properties of serum, was that of Dr. Thomas Lumsden, who showed the differing effects of treating cancer cells and normal tissues with cytotoxic sera. Accounts of his work at the Lister Institute have from time to time appeared in our columns.[1] From the medical point of view the tests available for detecting small quantities of arsenic are already sufficiently delicate, but it was interesting to note that an experiment demonstrated by Mr. A. A. King has been made the basis of a technique by which amounts as small as 0.00001 mg. may be estimated. The Gutzeit method is used for the preparation of a mercury-arsenic stain upon filter paper, which has been sensitised with pure mercuric chloride. When the paper is viewed in a beam of ultra-violet light transmitted through Chance's ultra-violet glass, which excludes visible radiation, the unchanged mercuric chloride fluoresces blue, while the mercury-arsenic stain stands out as a black disc. Mr. King also showed that under the stimulus of ultra-violet light distilled water is strongly fluorescent. By the use of the most refined distillation processes this fluorescence is considerably diminished, but so far it has not been possible to obtain a distilled water in which it is absent—which is free, that is to say, from any impurity. The application of ultra-violet light to microphotography was demonstrated by Mr. J. E. Barnard, F.R.S., who showed absorption spectra obtained by transmitting ultra-violet light through very thin layers of certain culture media. A series of photographs of bacilli made with ordinary and ultra-violet light showed the improvement in definition gained by using the shorter radiations. An apparatus for recording radiation from the sky, prepared by the Cambridge Instrument Company, was of interest to the radiologist. It consisted of a photo-electric cell so connected in a circuit of appreciable electrical capacity that the frequency of the discharge in the circuit depends upon the intensity of the radiation falling upon it. Experiments on the physiology and genetics of the covered smuts of oats and barley were shown by Mr. S. Dickinson, of the Rothamsted Experimental Station, Harpenden. In the vegetative state these fungi consist of uninucleate hyphæ of two genders (sexes) and infection of the seedling plant occurs only in the presence of both genders. The heterosexual attraction of the genders, regardless of species, was neatly demonstrated. Mr. Dickinson has developed a special technique for manipulating single hyphæ. He takes advantage of the surface-tension effects arising where an extremely thin glass rod is dipped into agar and then slightly withdrawn. The glass rod is mounted on a fine adjustment device by which it may be moved to any part of a microscope's field and by its aid the movement of a single hypha to any desired position is comparatively easy. This ingenious method may have some application to bacteriology. The value of the bolometer as a recorder of radiant heat was demonstrated by Mr. H. Dewhurst, who has invented a new way of making the instrument. A collodion film, sufficiently thin to show strong interference colours, is stretched over an annular disc of sealing wax which contains two inlaid metal contacts; a narrow strip of bismuth, about one-millionth of a centimetre in thickness, is then deposited by electrical evaporation across the film. The use of these extremely thin bismuth strips increases the rapidity with which the bolometer responds to radiant heat and correspondingly increases its usefulness. The British Thomson-Houston Company had a beautiful exhibit of a new type of electric discharge, whilst of general interest were the tie-rods shown by Sir Robert Hadfield, F.R.S., and made of high tenacity non-corrodible steel, which are being used at St. Paul's Cathedral to replace the original wrought-iron bars employed by Sir Christopher Wren. The forthcoming total eclipse of the sun was represented by models made by Dr. E. H. Rayner, of the National Physical Laboratory. One of these, a three-dimensional model of the shadow near the earth's surface, has been prepared for the Radio Research Board to indicate the plan position of the intersection of the moon's shadow with the region known as the Heaviside layer, about 60 miles above the surface of the earth. It is thought that the marked difference between the transmission of wireless waves during the daytime and at night is connected with this layer, concerning which more information is likely to be gained by observation during the eclipse.

LAVAGE OF THE SEMINAL VESICLES

IN a paper by the late Dr. R. Keith Fraser and Mr. L. B. Goldschmidt on the surgical management of surgical vesiculitis, which appeared in our columns some months ago,[1] the authors discussed the value of vasostomy as a method of treatment of this troublesome condition. They came to the conclusion that the use of this operation shortened the average length of treatment by 75 per cent., and often converted a case which was not responding to conservative measures into one that responded. It is interesting to compare with this the conclusions reached by Dr. Hermann L. Kretschmer, published in a paper read before the Genito-urinary Section of the Academy of Medicine, New York, last November. In this paper the author reviews 66 cases seen at his consulting-room on whom the operation had previously been performed. Of these 66 cases 12 had been operated upon twice, and one three times. The cases were carefully examined and questioned as to the relief that the operation had afforded. Thirty-three of them stated definitely that they had obtained no relief whatever; 11 declared that since the operation the symptoms had ceased; eight gave indecisive replies, and only four were of the opinion that they had been cured. The question of sterility as an end-result was also investigated; two of the patients were physicians who definitely stated that the operation had rendered them sterile; repeated examination of condom specimens had shown a complete azoospermia, abundant spermatozoa having been present previous to the operation. The possibility of sterility following the operation of vasostomy is, therefore, a point to be considered. As a result of a careful examination of the genital tract of the 66 cases, two observations were made by the authors. The first of these was that in a very large number of cases definite lesions existed in the anterior urethra, either in the nature of actual strictures or of soft, easily bleeding granulations. The second noteworthy feature was the large number of cases showing extensive pathological changes in the prostate and seminal vesicles, changes manifested by hardness, tenderness, or swelling. Forty-seven out of the 66 patients showed these alterations, the rectal findings being normal in only ten. In ten cases no rectal examination was made. Summarising Dr. Kretschmer's peutic value Mr. Pfund makes no reference to the use of vitaglass for the construction of solaria. This *glass it is true* is opaque to rays shorter than 2700 A.U, but it unlike the cellulose compounds which slowly become more and more opaque, has the advantage of remaining transparent for the longer rays In the second part of his paper Mr Pfund describes in some detail the actinometer he has designed for comparing the antirachitic efficiency of various sources of U-V rays His method depends upon the excitation of fluorescence in uranium glass by the U-V component of a mixed source of light The green fluorescent light is compared spectroscopically with the light from an incandescent filament lamp having a suitable filter, the luminous fields due to the two sources of light being focused in apposition. The appearance is thus somewhat like that seen in a polariscope matching of the two fields being obtained by varying the current flowing through the incandescent filament The relative efficiency of different sources of U-V rays may thus be referred to the current consumption of the filament lamp necessary to obtain a match with the fluorescence excited by the U-V rays in question While it may be very useful experimentally, this actinometer is hardly likely to be of so much clinical value as the inventor anticipates The recent discovery by Rosenheim and Webster of the intensely antirachitic potency of irradiated ergosterol will surely lead to the widespread use of this simpler and less expensive form of therapy in the treatment of rickets

[1] THE LANCET, 1926, ii., 749.

THE BRITISH MEDICAL ASSOCIATION'S ANNUAL MEETING

THE British Medical Association s ninety-fifth annual meeting is to be held at Edinburgh in July under the presidency of Sir Robert Philip It will begin with the annual representative meeting on Friday July 15th and the three weekdays following, whilst the work of the meeting will end with papers and discussions at the Scientific Sections from Wednesday the 20th to Friday the 22nd The gathering is to be made the occasion of the Edinburgh celebrations of Lord Lister s centenary and Lord Balfour, F R S will preside at a meeting in the McEwan Hall on the evening of July 20th when short addresses will be given by Sir Watson Cheyne, F R S. Prof Harvey Cushing of Harvard University, Prof T. M Tuffier of Paris and Dr. James Stewart of Halifax, Nova Scotia. Relics of Lister's life and work will be on view for some days in the upper library of the old university, and a Lister memorial volume has been prepared, of which copies will be distributed. The other arrangements include the annual general meeting on Tuesday July 19th the conference of honorary secretaries on the 20th, and the annual dinner on the 21st The official religious service will be held in St Giles s Cathedral on July 19th at 4 30 P M From the 18th to the 22nd there will be the usual exhibition of surgical appliances, foods, drugs, and books, whilst the day after (Saturday the 23rd) will be given over to an excursion by special train to St Andrews Many other arrangements have been made which will enable members to explore a neighbourhood which is fascinating from innumerable standpoints In the various scientific sections the subjects of discussion include the results of insulin therapy in diabetes the treatment of lobar pneumonia, and the pathology and treatment of pernicious anæmia, which will be dealt with by the Section of Medicine, and tuberculosis of the kidney toxic goitre and chronic appendicitis at the Section of Surgery at which papers will also be read on the rational treatment of infected wounds and on burns There will be two big discussions by the Section of Obstetrics and Gynæcology the first on the relation of pregnancy to general diseases and the second on the hygiene of menstruation in adolescents; a number of papers on other topics will also be given The Section of Pathology and Bacteriology will hold three discussions two of them in conjunction with the Section of Comparative Medicine at which a number of speakers will discuss immunity and other problems in the two fields. The first meeting of this section will be devoted to consideration of growth in its pathological relations The other subjects to be dealt with by the sections are very numerous; some of them are of exceptional interest and we propose to set out the programme at more length in a later issue In the meantime enough has been said to indicate the many-sided character of the Association's congress and to suggest that this meeting in the Scottish capital promises to be especially attractive

THE DOGS PROTECTION BILL.

SEVEN years ago, when moving the second reading of the Dogs Protection Bill in the House of Commons of which he was then a Member, Lord Banbury of Southam claimed THE LANCET as a supporter The article on which the claim was based appeared in our issue of May 31st 1919 and stated that " the experimental use of dogs has advanced our knowledge and has been of benefit to suffering humanity." These lines were not quoted in the House of Commons the speaker contenting himself with citing the next passage wherein it is admitted in so many words that certain results might have been obtained otherwise —of course in the light of later information For scientific developments may at any time enable workers to undertake analogous researches on lowlier animals and all rejoice when the use of any animal as a test object can be superseded by other technique or rendered unnecessary by new knowledge We pointed out at once the misrepresentation of ourselves but unavailingly, for in 1924 Lord Banbury, when proposing the second reading of a similar measure in the House of Lords again brought forward THE LANCET as backing him We protested to Lord Banbury against this repetition of the inaccuracy with an explanation (that should have been unnecessary) of the attitude of THE LANCET But it seems that he cannot forgo the value to his cause of declaring that his views have received our support, and whereas formerly he did at least quote our statement correctly he no longer troubles to do so In the current issue of *John Bull* he says that " it has been admitted in THE LANCET of May 31st, 1919, that the results obtained by experiments on dogs could have been equally obtained in other ways " There is no justification for this reading of our statement, and we should never have admitted anything so patently untrue

---

ROYAL MEDICAL BENEVOLENT FUND —At the last meeting of the Committee 34 cases were considered and £571 10*s* voted to 30 applicants The following is a summary of the new cases relieved

Daughter aged 62, of M R C S who died in 1876 Only income is a pension of £50, as the sister with whom she was living died recently and her pension died with her At present applicant is living with an invalid niece Voted £36 in monthly instalments

Widow, aged 64 of M R C S who died in 1892 Owing to ill health and age has been advised to give up her nursing with which she supported herself Daughter aged 35 is married with two children, and is unable to assist the applicant £7[illegible] was received from nursing in the past twelve months Voted £36 in 12 monthly instalments

Widow, aged 69 of M R C S who died last year Has two sons who are married, and is staying at present with the eldest one but neither son is in a position to give financial assistance Voted £36 payable in 12 monthly instalments

Daughter, aged 60 of M R C.S who practised in London and died in 1913 Lives in Paris and has supported herself by teaching and translating Owing to illness has not been able to meet expenses Voted £26

Wife aged 41 of M B who was helped by the Fund in February and August last year as he is trying to build up a practice in a small way Applicant is working in a small post on commission and does not make sufficient to cover expenses There are two daughters who are at school and have bursaries their outfit having been provided by the Church Voted £12 towards repaying debts

Subscriptions may be sent to the Hon. Treasurer Sir Charters Symonds at 11, Chandos-street, Cavendish-square London, W 1 condition has been overlooked, the circular adds an "etc" under which the certifying surgeon might, we suggest, include cases of myopia of a degree over (say) 20 dioptres, whose visual acuity may still be as good as (say) 6/36 We think the circular will be of service to the certifying surgeon who is required not only to state the degree of visual acuity in each eye of any applicant for State aid, but to give the nature and extent of the visual defects present, and also to state his own definite opinion, formed after due consideration of all the visual conditions, that the person is too blind to perform work for which eyesight is essential.

MEDICAL EXAMINATION BEFORE MARRIAGE

SHOULD a medical examination before marriage be made obligatory? This question, the title of an article by Dr Georges Schreiber, secretary-general of the Societe Française d'Eugénique, in the February issue of the *World's Health*, has aroused considerable interest in different countries and has provoked a correspondence in that journal which is still continuing In the original article Dr Schreiber reviewed the present situation in various parts of the world, mentioning specially those countries in which a medical examination or certificate before marriage is obligatory, and those in which institutions for facilitating such an examination have been provided, although it has not been made obligatory In France a Bill making a pre-nuptial medical certificate compulsory has been drafted by Prof Pinard, but no definite action has yet been taken Dr Schreiber himself advocates an obligatory certificate, but with optional examination Referring to Dr Schreiber's remark that it was regrettable that eugenic legislation in the Scandinavian countries left tuberculosis out of consideration, Dr Soren Hansen of Copenhagen points out, in the March issue of the same journal, that the death-rate from tuberculosis in Denmark has in the last 25 years fallen from more than 20 to less than 10 per 10,000, probably the lowest rate in any European country They prefer not to brand the tuberculous, but to fight the disease by spreading knowledge as to its nature and how to avoid it Dr Apert, of the Hôpital des Enfants Malades in Paris, pronounces himself in favour of persuasion through health education rather than coercion, instancing prohibition of alcohol as an example of the evil effects of compulsion, and pointing out that laws, unless supported by public opinion, cannot alter customs Prof Vladislav Ruzicka, of Prague, in another letter, states that he himself had drafted a Bill, which was approved by the Czechoslovak Eugenics Society requiring a medical certificate before marriage, but this Bill was rejected The proposed legislation required a compulsory medical certificate as an indispensable legal condition of the marriage contract, the certificate to be signed by an authorised physician and to state that the parties were free from any defect or disease which would interfere with marriage Some of the objections urged against this Bill were that it would not protect illegitimate children, and that unwillingness to submit to a medical examination might increase illicit relations and hence the number of illegitimate children Prof Ruzicka, in answer to this, quotes a German authority who has shown that every condition added to the marriage contract has been followed by a reduction in the number of illegitimate births In the May number the correspondence is continued by Dr Stella Churchill, who emphasises the need for public propaganda on this subject She considers that pre-parental responsibility should form part of sex-teaching in the schools and does not advocate a medical certificate without examination She believes that voluntary limitation of families would be the obvious sequence of a medical examination before marriage and foresees the abolition of "the present rather absurd code about professional secrecy—a code which inflicts misery and hardship on innocent victims" In the same issue Prof Jeanselme, President of the French National League against Venereal Diseases, pronounces himself in favour of a certificate covering such infirmities as tuberculosis, venereal disease, confirmed alcoholism, epilepsy, and insanity, but he believes, as Dr Churchill does, that education must precede compulsion He thinks that the task of educating the public should be shouldered by the leagues against venereal diseases, tuberculosis, alcoholism, and so on He also points out some of the difficulties in the way of granting certificates and considers that, if the principle is to be adopted, the certificate should be required of both sexes

A pamphlet issued by the Russell Sage Foundation of New York on the administration of the Wisconsin Marriage Law[1] throws some interesting sidelights on the practical administration of a law requiring medical certificates before marriage In August, 1913, Wisconsin enacted a law under the terms of which no man applying could receive a marriage licence unless provided with a physician's certificate which attested that he was free from acquired venereal disease A study of the effects of this law was undertaken by the Russell Sage Foundation in 1920 and concluded in 1925 The main conclusions reached were that the law has had educational value, through newspaper discussion and through the fact that large numbers of men receive a warning as to the dangers of venereal infection at a time when they are most likely to need it It has been a real factor in inducing men who expect to marry to make sure that they are fit To some extent the required examination has caused postponement of marriage A minority of physicians issue certificates without any form of physical examination, but most examinations appear to be thorough, and use is made of the State's free laboratory service A serious obstacle to the successful operation of the law is that it never had the medical profession actively behind it because their cooperation was not sought in drafting the Bill Of the 364 physicians who commented on the law, however, nearly two-thirds expressed generally favourable opinions The investigators consider that in the present state of public opinion it is practically impossible to subject women to compulsory examination in order to establish their freedom from venereal infection. The law has been handicapped by its very defective requirements and by the absence of any provision for State supervision No attempt is being made to eliminate the defects and no steps are being taken to win the cooperation of the medical profession Repeal was avoided only by a narrow margin in 1923, and the State Medical Society neither favoured nor opposed the repeal

WORKING STANDARDS IN HELIOTHERAPY

RADIOLOGISTS using ultra-violet rays are confronted by the same problem of practical and accurate measurement of the composite radiation as has been encountered in the case of X rays The difficulty of interpreting with any precision the dosage employed by various workers in this field is complicated, in the case of clinical U–V therapy by the wide variations of individual susceptibility In the April *Bulletin* of Johns Hopkins Hospital Mr A H Pfund describes his attempts to provide a standard measuring instrument whose range of sensitivity to U–V rays corresponds with the effective wave-lengths in the treatment of rickets The first part of his paper deals with cellulose compounds as material for windows transparent to U–V rays Cellophane, which proved to be the most efficient, has the advantage of being waterproof and of darkening only very slowly under the action of the rays It transmits 50 per cent of rays at 2550 Angstrom units and between 60–75 per cent in the region of 3000 A U, the effective end of the sun's spectrum While pointing out the opacity of ordinary glass for the U–V rays of therapeutic value, Mr Pfund makes no reference to the use of vitaglass for the construction of solaria This glass, it is true is opaque to rays shorter than 2700 A U , but it, unlike the cellulose compounds which slowly become more and more opaque, has the advantage of remaining transparent for the longer rays In the second part of his paper Mr Pfund describes in some detail the actinometer he has designed for comparing the antirachitic efficiency of various sources of U–V rays His method depends upon the excitation of fluorescence in uranium glass by the U–V component of a mixed source of light The green fluorescent light is compared spectroscopically with the light from an incandescent filament lamp having a suitable filter, the luminous fields due to the two sources of light being focused in apposition The appearance is thus somewhat like that seen in a polariscope, matching of the two fields being obtained by varying the current flowing through the incandescent filament. The relative efficiency of different sources of U–V rays may thus be referred to the current consumption of the filament lamp necessary to obtain a match with the fluorescence excited by the U–V rays in question While it may be very useful experimentally, this actinometer is hardly likely to be of so much clinical value as the inventor anticipates The recent discovery by Rosenheim and Webster of the intensely antirachitic potency of irradiated ergosterol will surely lead to the widespread use of this simpler and less expensive form of therapy in the treatment of rickets

THE BRITISH MEDICAL ASSOCIATION'S ANNUAL MEETING

The British Medical Association's ninety-fifth annual meeting is to be held at Edinburgh in July under the presidency of Sir Robert Philip It will begin with the annual representative meeting on Friday, July 15th, and the three weekdays following, whilst the work of the meeting will end with papers and discussions at the Scientific Sections from Wednesday the 20th to Friday the 22nd The gathering is to be made the occasion of the Edinburgh celebrations of Lord Lister's centenary, and Lord Balfour, F R S , will preside at a meeting in the McEwan Hall on the evening of July 20th when short addresses will be given by Sir Watson Cheyne, F R S , Prof Harvey Cushing, of Harvard University, Prof T M Tuffier, of Paris and Dr James Stewart, of Halifax, Nova Scotia Relics of Lister's life and work will be on view for some days in the upper library of the old university, and a Lister memorial volume has been prepared, of which copies will be distributed The other arrangements include the annual general meeting on Tuesday, July 19th, the conference of honorary secretaries on the 20th, and the annual dinner on the 21st The official religious service will be held in St Giles's Cathedral on July 19th at 4 30 P M From the 18th to the 22nd there will be the usual exhibition of surgical appliances, foods, drugs, and books, whilst the day after (Saturday the 23rd) will be given over to an excursion by special train to St Andrews Many other arrangements have been made which will enable members to explore a neighbourhood which is fascinating from innumerable standpoints In the various scientific sections the subjects of discussion include the results of insulin therapy in diabetes, the treatment of lobar pneumonia, and the pathology and treatment of pernicious anæmia, which will be dealt with by the Section of Medicine, and tuberculosis of the kidney, toxic goitre, and chronic appendicitis at the Section of Surgery, at which papers will also be read on the rational treatment of infected wounds and on burns There will be two big discussions by the Section of Obstetrics and Gynæcology, the first on the relation of pregnancy to general diseases, and the second on the hygiene of menstruation in adolescents , a number of papers on other topics will also be given The Section of Pathology and Bacteriology will hold three discussions two of them in conjunction with the Section of Comparative Medicine, at which a number of speakers will discuss immunity and other problems in the two fields The first meeting of this section will be devoted to consideration of growth in its pathological relations The other subjects to be dealt with by the sections are very numerous , some of them are of exceptional interest and we propose to set out the programme at more length in a later issue In the meantime enough has been said to indicate the many-sided character of the Association's congress, and to suggest that this meeting in the Scottish capital promises to be especially attractive

THE DOGS PROTECTION BILL.

Seven years ago, when moving the second reading of the Dogs Protection Bill in the House of Commons, of which he was then a Member, Lord Banbury of Southam claimed The Lancet as a supporter The article on which the claim was based appeared in our issue of May 31st, 1919, and stated that " the experimental use of dogs has advanced our knowledge and has been of benefit to suffering humanity." These lines were not quoted in the House of Commons, the speaker contenting himself with citing the next passage wherein it is admitted in so many words that certain results might have been obtained otherwise —of course, in the light of later information. For scientific developments may at any time enable workers to undertake analogous researches on lowlier animals, and all rejoice when the use of any animal as a test object can be superseded by other technique, or rendered unnecessary by new knowledge We pointed out at once the misrepresentation of ourselves, but unavailingly, for in 1924 Lord Banbury, when proposing the second reading of a similar measure in the House of Lords, again brought forward The Lancet as backing him We protested to Lord Banbury against this repetition of the inaccuracy with an explanation (that should have been unnecessary) of the attitude of The Lancet But it seems that he cannot forgo the value to his cause of declaring that his views have received our support, and whereas formerly he did at least quote our statement correctly. he no longer troubles to do so In the current issue of *John Bull* he says that " it has been admitted in The Lancet of May 31st, 1919, that the results obtained by experiments on dogs could have been equally obtained in other ways " There is no justification for this reading of our statement, and we should never have admitted anything so patently untrue.

Royal Medical Benevolent Fund —At the last meeting of the Committee 34 cases were considered and £571 10s voted to 30 applicants The following is a summary of the new cases relieved

Daughter aged 62, of M R C S who died in 1876 Only income is a pension of £50, as the sister with whom she was living died recently and her pension died with her At present applicant is living with an invalid niece Voted £36 in monthly instalments

Widow, aged 64 of M R C S who died in 1892 Owing to ill health and age, has been advised to give up her nursing, with which she supported herself Daughter, aged 35, is married with two children, and is unable to assist the applicant £75 was received from nursing in the past twelve months Voted £36 in 12 monthly instalments

Widow, aged 69 of M R C S who died last year Has two sons who are married and is staying at present with the eldest one but neither son is in a position to give financial assistance Voted £36 payable in 12 monthly instalments

Daughter, aged 60, of M R C S who practised in London and died in 1913 Lives in Paris, and has supported herself by teaching and translating Owing to illness has not been able to meet expenses Voted £26

Wife, aged 41, of M B who was helped by the Fund in February and August last year as he is trying to build up a practice in a small way Applicant is working in a small post on commission, and does not make sufficient to cover expenses There are two daughters who are at school and have bursaries their outfit having been provided by the Church Voted £12 towards repaying debts

Subscriptions may be sent to the Hon Treasurer, Sir Charters Symonds, at 11, Chandos street, Cavendish square, London, W 1

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions

CCXXIV—THE MEDICAL TREATMENT OF CANCER OF THE STOMACH

IN no form of malignant disease are the results more depressing than in carcinoma of the stomach The absence of early symptoms gives the patient little warning and the obscurity of the physical signs often leads to delay in diagnosis It must be added that, even when diagnosis has been made very early the results of treatment whether surgical, medical, or radiological, are seldom less disappointing

In a later paragraph it will be laid down that surgery plays a most important part in the treatment of gastric carcinoma There are, however, many cases which are unsuitable for operation on account of the patient's general condition or the extent of the local lesion, there are others where surgery is not indicated even apart from these factors, and there are yet others which call for medical treatment when surgery has failed The medical treatment of cancer of the stomach is therefore a problem frequently before every medical practitioner

Curative Measures

Attempts at curative treatment fall under three headings (*a*) surgical, (*b*) medical, and (*c*) radiological, two of these forms of treatment being frequently combined

Surgical —Excision of the primary growth still presents the greatest hope of cure It should be attempted whenever possible In this connexion it must be remembered that pyloric growths producing gross gastric retention, with dilatation of the stomach and profuse vomiting, are not infrequently small in size and relatively easy to remove surgically

Medical —Curative medical treatment usually takes the form of intravenous injection of salts of the heavy metals, such as copper, lead, and selenium Great caution is necessary, and the results so far have been interesting rather than encouraging Attempts to cure cancer of the stomach by special diets have been uniformly unsuccessful The Wassermann reaction should be determined in every suspected case, benign gummata having occasionally been mistaken for malignant growths

Radiological —Deep X ray therapy may be tried, but should never be substituted for surgery in operable cases I have frequently seen amelioration of symptoms follow its employment, but never cure The implantation of radium or radon by a minor surgical operation is often a preferable form of radiological treatment, the growing edge of the carcinoma can in this way be attacked and localisation of treatment is easier

Palliative Measures

The treatment of symptoms and complications again falls under the heading of surgical, medical, and radiological

Surgical —The commonest use of surgery in cancer of the stomach is for the prevention of obstruction Remembering that pyloric obstruction is a frequent cause of death in these cases, the practitioner will be at pains to secure a short-circuiting of pyloric growths at a stage when such a procedure is practicable The selection of such a site for the stoma that subsequent blockage does not occur is a matter of surgical technique which is outside the scope of the present article Surgical operations for the prevention of pain by nerve-section are infrequently required

Medical —Here two main aspects of the disease overshadow all others, they are (1) obstruction, and (2) pain

(1) *Obstruction* —The necessity for the surgical prevention of obstruction has already been emphasised Cases are met with fairly often in which the extent of the disease or the patient's low condition preclude such operations Obstruction of the cardiac orifice is not here considered, its treatment does not materially differ from that of œsophageal obstruction

In inoperable pyloric obstruction the treatment of greatest value and most frequently neglected is *gastric lavage* It cannot be over-emphasised that gastric lavage is a procedure which patients, with very little practice, can themselves perform with ease and considerable advantage A soft rubber tube, of about the calibre of the little finger and if possible furnished with a single large opening half an inch above the tip, should be selected The patient should be taught to pass this at first daily, later as often as required, and the stomach should be washed with normal saline until relatively clean and empty Sodium bicarbonate solution is useful if there is any excess of mucus, and opiates may be added later by this route if there is an indication for them Gastric lavage should never be delayed until the time when it is an increased burden to the patient, he should, on the contrary, learn its value in the early days just as a patient in the early days of an attack of pneumonia will learn to appreciate the value of oxygen and call for it gladly, even in the delirium preceding the crisis

Diet is of great importance Patients with carcinoma are seldom hungry and there is no evidence that forced nutrition has any effect in delaying the progress of their malady If therefore hunger is allayed there is no reason for attempting to provide a large diet The *problem of obstruction remains* the most prominent Foods containing cellulose, such as green vegetables, brown or branny breads, fruits other than orange-juice and soft bananas should be excluded together with meat or fish in any large pieces, unless *obstruction in any degree be absent* Soups, carbohydrate gruels, milk, glucose solutions, and orange-juice are the foods of choice when obstruction is threatened, and alcohol is, in my opinion, a most valuable adjunct in these cases on account of its calorie value, sedative effects, and ready assimilation

There is nothing illogical in the combined use of such foods with gastric lavage, a partially obstructed stomach frequently relieved by lavage will allow the progress of more fluid than such a stomach treated in any other way In inoperable cases of severe pyloric obstruction nutrient enemata must be employed to relieve thirst

(2) *Pain* —Much of the pain and discomfort of cancer of the stomach is due to obstruction, and should be avoided by the measures described above There remain the pains of nerve involvement or due to the spread of the disease elsewhere Analgesics, such as bromides, pyramidon, allonal, and diacetate are often valuable in the early stages Luminal is sometimes very effective in controlling nausea and vomiting

When the diagnosis is quite definite and pain and discomfort are prominent, there is little to be gained by delaying the use of opiates In my experience, much needless suffering is caused through the mistaken belief that a stage in the disease will be reached when morphia in any form will become ineffective As regards cancer of the stomach, this is a profound error It is seldom necessary to give more than small doses of omnopon, or of such time-honoured preparations as tr chloroformi et morphinæ co or tr opii, in order to secure ease for the patient, provided that gastric lavage is used to allay the symptoms of obstruction

The personal attitude of the doctor towards his patient is at no time of greater importance than in these cases, and a steady optimism in the face of tragedy is both helpful to the patient and justified by the progress of medical science

UNIVERSITY COLLEGE, LONDON, AND MEDICAL EDUCATION.

Being a Centenary Address delivered at University College on May 13th, 1927,

BY SIR JOHN ROSE BRADFORD, K.C.M.G., M.D., F.R.S.,
PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON, EMERITUS PROFESSOR OF MEDICINE IN UNIVERSITY COLLEGE.

IT is perhaps fitting seeing the part this College has played and is playing in medical education that one of the centenary addresses should be devoted to a subject that must necessarily be of considerable interest to the community when we consider the ever-increasing importance of the part taken by medicine in our daily life even when we regard ourselves as being in vigorous health, to say nothing of the services required when disease is present or threatened Our founders were not only animated by high ideals but must also have been in some respects not entirely devoid of interest in what are sometimes called practical aims Thus at the foundation of the College there were but two faculties, one of arts and laws and one of medicine. and here the history of the College is not unlike that of the history of all human activities From very early times man has not only been profoundly interested in the study of those activities of the mind that are embraced in what is now understood by the term "faculty of arts" but also from the earliest times he has recognised that if he is to survive he must regulate his life according to his knowledge of the facts of Nature and he must also enter into regulated relations with his fellow men In founding this College with a faculty of arts and with a faculty of medicine, our founders recognised these fundamental principles and probably there is nothing very remarkable in this but what was remarkable, and what I hope to show in this address, is the extraordinary breadth of view that stimulated them and what a grand conception they had as to the real requirements necessary for the adequate study of medicine Further, I shall hope to show that this College has been faithful to the trust imposed upon it by its founders and that in the past century it has not been unworthy of this trust

Problems of Medicine

Medicine as a study and branch of knowledge has many attractions and amongst these may be mentioned the very wide range of its scope its extraordinary diversity, and its numerous relations with other varieties of human activity This, *no doubt* is one of its greatest dangers inasmuch as it leads frequently to the presentation of such complex issues that much courage is required in order to overcome the feeling of hopelessness and possibly even sometimes of despair that may be engendered The problems of the statesman. of the soldier and of the lawyer are universally recognised as being often of such difficulty as almost to defy solution but the problems that beset the follower of medicine are certainly not of lesser difficulty and require for their solution no less ability and no less degree of adequate study and preparation After all the statesman, the soldier, and especially the lawyer, has to pit his intelligence against that of another human being His problems are difficult enough, but they are in the main and essentially problems set by man The doctor, even the humblest and the least well-equipped by education, perhaps has all his problems set to him by Nature This does not add to the ease of their correct solution, further there is no court of appeal, and Nature certainly is, and always has been a stern judge. For these reasons it is surely of paramount importance that medical education should be organised on the best possible lines and that the future practitioner should at any rate have the opportunity of acquiring an adequate conception of the real nature of his work before he becomes immersed in and possibly overwhelmed by. the so-called routine of medical practice

We talk of the principles and practice of medicine or the science and art of medicine, just as the soldier talks of the science and art of war, and these are not fanciful distinctions but matters of the greatest importance A doctor who neglects the principles or science of medicine is not likely to have any greater success than a general who violates a fundamental principle of the science of war, but in both cases the judgment meted out will probably be professional rather than lay, inasmuch as the layman necessarily is often unable to appreciate the real issue. A practitioner of the art of medicine who does not regulate his art by his science often escapes criticism by the supposition commonly entertained that medicine is only an art and not a science and that there is something mysterious about disease that removes it from the category of things and leaves an opportunity for the action of chance. or of some other equally vague conception In other words. it is not realised that our failure or our uncertainty is due to our want of knowledge or possibly to the misapplication of our knowledge

Whereas the art of medicine is very ancient and teachers of this art flourished many thousands of years ago the science of medicine is of comparatively recent origin Hippocrates as we all know, was a great exponent of the art of medicine and we are still indebted to his genius for much of our knowledge even in the twentieth century medicine The science of medicine may be said to date from Harvey. a matter of some 300 years, but the application of the science of medicine to the art of medicine is a matter of much more recent date and it is here. I think, that University College has played a not undistinguished part I would like to say at the outset that it is not a question so much of any particular discovery having been made within these walls or by those connected with the College although there have been many such, and some of them great but rather the broader question of the relation of the science of medicine to other sciences and to the art of medicine and perhaps the most important of all the development of scientific methods and of the scientific type of mind in the pursuit of the art of medicine by the practitioner in his daily work It may, perhaps be said that in the pursuit of the science of medicine the disease forms the focus of attention. and in the pursuit of the art of the medicine the patient must be the first consideration Yet little or no success is likely to be achieved if the art be practised with unscientific methods or in an attitude of mind that is not familiar with the law that like causes produce like results and that the numerous apparent contradictions that we see in our daily work are not real exceptions but only apparent ones, due to the fact that the conditions are not really the same although they may at first sight seem to be so Medicine could give many illustrations of the truth of the great principle of *déterminisme*, laid down with such insistence in the writings of the French physiologist Bernard

Medical Training a Hundred Years Ago

The really great clinicians of the past who pursued the art of medicine, and were in truth great artists were nevertheless men who observed with scientific method and controlled their observations with scientific reasoning, hence the value of their results. and in many cases their successors through the centuries have only been able to admire their skill and marvel at the results they achieved with the limited means at their command These great men attracted followers and thus the teaching of medicine commenced; the disciples attended the Master and listened to what he had to tell them and doubtless they tried to imitate his methods It is scarcely an exaggeration to say that the teaching of medicine. in England at any rate had not advanced very much beyond this stage at the time of the foundation of this College

This country has had many great clinicians, and some of them have been physicians or surgeons attached to the hospitals of this country of ancient foundation, and such men, like the ancients attracted students who followed their practice in the wards, and in this way acquired some clinical knowledge. They "walked the hospitals," a phrase that came to be descriptive of a certain stage in the career of the student of medicine, and I am not sure that some of the great public are not still under the impression "that walking the hospitals" forms the major part of the educational programme of the present-day student.

The student, besides walking the hospital, did two other things, he was apprenticed to some practitioner, and under such circumstances might or might not acquire medical knowledge that would be of service to him in later life. Unquestionably he acquired a varied knowledge of human nature, which is one of the most important assets that he will require in his after life as a practitioner. The student also often attended some private school of anatomy, of which there were many, and here I may mention that I am old enough to remember the last of these, and my own father attended as a young man one of the most celebrated and notorious of such schools.

I do not propose to criticise these methods of education, they must have possessed some value, otherwise the history of medicine in this country would not contain the honoured names that it does. What I want to emphasise is the isolated and secluded character of the instruction given, and how it was entirely directed to the production of a practitioner. As an apprentice, as a student at an anatomy school or as one walking the hospitals, the ordinary student had no opportunity of widening his outlook on life, or of coming into contact with other branches of learning. It is true that at the ancient seats of learning in this country there were very small numbers of men who, having studied in the humanities, subsequently embarked on medicine, and some of the greatest names in British medicine are those of such men but the ancient universities did not afford facilities for the prosecution of medicine, and the great developments that have taken place in these old universities are subsequent to the foundation of this College, and are by no means unconnected with the developments that have been initiated here. It is also true that certain of the London hospitals had schools directly associated with them where members of the hospital staff gave instruction, not only in clinical subjects, but also in certain other subjects, especially anatomy.

Sir George Thane, our chairman, pointed out in an introductory address given by him in 1879 in this place, that in the year 1828 medical education in London was practically limited to providing the instruction required by the licensing bodies and this was not of a very extensive character. Thus the College of Surgeons required that a candidate for the diploma should have been engaged for at least six years in the acquisition of professional knowledge, and that he had attended certain courses of instruction—i e , three courses of anatomy, two of dissections and demonstrations, one of chemistry and one of midwifery, one of materia medica and botany, and one of practice and theory of physic. Further, he had to attend for one year the surgical practice of a recognised hospital. To fulfil these requirements the future practitioner of medicine became an apprentice to a practitioner, and not infrequently he entered on this when only 15 or 16 years of age, and came to London only for one or, at the most, two years, and there followed all the courses of instruction provided by the hospital or private school concurrently. Thus he went to such lectures as he was compelled to attend, he dissected, and he "walked the hospital or hospitals," all at the same time.

The London hospitals that had schools attached to them at this period were St Bartholomew's, St Thomas's, Guy's, and the London. Not infrequently the student attended at more than one school, and still more frequently he attended one of the private schools, owing to the reputation and fame of some individual teacher, this applied, perhaps, more especially to the schools of anatomy that occupied a very prominent place in the medical curriculum. The London hospitals at this period included amongst their staffs physicians and surgeons not only distinguished for their knowledge, but also men who were able teachers, and men who were capable exponents of some of the sciences ancillary to medicine. Medicine has not only received benefits from science but some of the results of so-called pure science have been obtained from the researches of men who were primarily practitioners of the art of medicine, and hence it is not strange that teachers of such subjects as chemistry and botany should have been found from the ranks of medicine.

The Limited Outlook

Nevertheless, the system of medical teaching here outlined as that prevalent when this College was founded was profoundly unsatisfactory, more especially from two points of view. In the first place, it was not only inadequate and imperfect, it also entirely lacked organisation and systematisation, but it also suffered from a much more serious defect than this, in that the educational problem was looked at from a far too narrow point of view. The aim was to produce an efficient practitioner and this must necessarily always be the aim of any scheme of medical education, but this result is not likely to be achieved if a scheme of instruction is devised that isolates the student and confines his outlook.

A hundred years ago the outlook of the student was limited from childhood, he became an apprentice when little more than a boy, at a most impressionable age, and from that time onward his teachers were animated by the desire to direct their teaching solely to the supposed immediate practical requirements of the moment. Anatomy was taught by a surgeon from the point of view of the surgeon of that day—i e , for its direct practical utility. I remember in my own day a teacher of medicine saying that just as a cabman must know the anatomy of London so a doctor must know that of the human body. This is, of course, quite true, but the real point is whether that is the sole reason for the cultivation of anatomy by the medical student, whether he should be taught to confine his ambition to that of the cabman or whether there is likely to be any gain to him purely as a practitioner from having an opportunity at any rate of perceiving that the study of anatomy may be pursued from a different standpoint and with other and less limited aims.

It is of course an old and difficult question, this question of medical education, and the increase of knowledge does not make the problem any easier. Is disease to be recognised and treated by a kind of rule of thumb method, or is the student to be educated on lines that attempt to develop his intelligence so that he may be equipped to deal with the complex problems that will fall to his lot? I think our founders had no sort of doubt as to their views on this matter. They looked on medicine not only as a practical art of great importance to all of us, but they also regarded medicine as a branch of learning that should take its place with other learning in any university that deemed itself worthy of the name.

A Debt to Edinburgh

A hundred years ago there was, at any rate, one university in these islands where these views prevailed, and that was the University of Edinburgh, this is a fact of special interest to us, since the debt of this College to the University of Edinburgh, and especially so far as concerns the faculty of medicine is a great one. This debt is not only that many of the early professors and some of the greatest of them came to us from Edinburgh, but in addition, the organisation of the faculty of medicine, and, indeed, the whole conception of the foundation of the faculty and of the hospital, are strikingly similar to those carried out at Edinburgh a hundred years before the foundation of this College

Last year the University of Edinburgh celebrated the bicentenary of its Faculty of Medicine, and the tale of its foundation was then retold, and how the inspiration that led to its foundation was derived from the University of Leyden, when the great Boerhaave, perhaps the greatest of clinical teachers the world has seen, so influenced certain young Edinburgh men that on their return to their native city they took steps that led ultimately to the foundation of the Faculty of Medicine in 1726 We are not concerned here with the details of this story, interesting as it is, suffice it to say that the faculty was started without any special clinical facilities, and that some years later—i e, in 1738—the Edinburgh Royal Infirmary was founded in order to provide a suitable hospital to afford clinical facilities for the teaching of medicine As you will see, a similar course was pursued here, and our hospital is unique amongst the great teaching hospitals of London in that, like the Royal Infirmary of Edinburgh, it was founded, thanks to the energy of the young Faculty of Medicine and the generous wisdom of the governing body of this College, as a means to provide full opportunities for the adequate teaching of clinical medicine and surgery

I do not think it is an exaggeration to say that the foresight, wisdom, and courage of our founders must have been very considerable for them to have embarked on the foundation of a faculty of medicine, with a very ambitious scheme of development, with no hospital and no obvious likelihood of acquiring a hospital, without which the scheme must have come to nought They are certainly entitled to our profound admiration and their work should inspire their successors not to fall short of their high standard

New Ideals at University College

The Faculty of Medicine of this College, when constituted 100 years ago, included professorships in chemistry, natural philosophy, botany, comparative anatomy, anatomy and physiology, materia medica, medicine, surgery, and midwifery Medical jurisprudence and pathology were added almost immediately The courses of instruction extended from October to May and the curriculum extended over a period of four years It is, perhaps, scarcely necessary to dwell on the contrast afforded by such a scheme of education with that then in vogue in the medical schools of this country, but after all, although schemes and curriculum may have some value, the real determining factors are the ideals, the character, and the ability of those to whom is entrusted the carrying out of the scheme The professors appointed to teach these subjects were unquestionably a most distinguished body of men, each of whom had achieved distinction in the branch of knowledge committed to his charge, and some had become entitled to a fame that is undimmed by the lapse of a hundred years

Amongst these early professors, either appointed at the foundation or within a few short years of the opening of the College, may be mentioned In chemistry, Turner and Thomas Graham, in natural philosophy, Lardner, in botany, Lindley, in comparative anatomy, Grant; in anatomy and physiology, Jones Quain, Sir Charles Bell, and Sharpey, in materia medica, Anthony Todd Thompson; in medicine, Conolly and Elliotson, in surgery, Sir Charles Bell and Samuel Cooper; in midwifery, Davis and later, Murphy, in pathology, Sir Robert Carswell It is, perhaps, not surprising that with such teachers the Faculty of Medicine of this College, which began its teaching in October, 1828, one month before its sister Faculty of Arts and Laws, included some 300 students in the second year of its life This large number of students showed also that there was a real demand for teaching of the character provided and that it is not really true that the student's horizon is limited to the requirements of examining and licensing bodies The success of the Faculty of Medicine was thus assured from the very outset and this, notwithstanding the fact already mentioned that the hospital did not exist In order to provide some opportunities for the teaching of the clinical subjects a dispensary under the charge of the professors of medicine and surgery was opened in George-street, and this dispensary contained a very small number of beds, probably what we should now call casualty beds, for the relief of the more severe cases of sudden illness, and certain arrangements were made with a neighbouring hospital, the Middlesex, for our students to have the privilege of visiting its wards

It must be borne in mind that at this period 100 years ago, regular systematic clinical teaching was not in vogue in any London hospital, the students simply walked the hospital—i e, attended the visits of the medical officers and watched their proceedings, and more especially the operations in the case of the surgeons The surgeons of this time when, of course, there were no anæsthetics, had developed a technique in which great manipulative dexterity and a phenomenal rapidity of operation were essential to success It was the period of "brilliant operating," and the surgeons of the greatest skill and eminence operated in the presence of large audiences of students, and it was a point of honour to perform operations, especially amputations in a time limited to seconds I believe that prior to 1828 not only clinical professors but even clinical lectures were unknown in London although in the University of Edinburgh there was a chair of clinical surgery, and such instruction as the students received during their hospital visits was casual and Socratic or conversational in character. To remedy this grave defect in medical education, our founders instituted two clinical chairs, one in medicine and one in surgery, held by Sir Thomas Watson and Sir Charles Bell respectively, but since there was no hospital their lectures and instruction were given in the Middlesex Hospital

The point that requires emphasis is that this was the first step taken in organising and systematising the teaching of clinical subjects and the recognition that such subjects demanded the same methods of organised teaching that obtained in other branches of knowledge Naturally, the development of this method could not take place freely until the faculty had a hospital of its own, and so soon as this was obtained the further development of this organised clinical teaching took place and two special clinical professorships, known subsequently as the Holme professorships, were founded with the special object of training students in the observation and study of disease The fame of Robert Liston, who held for some 12 years the professorship of clinical surgery, was not a small factor in the success of this school as a centre of efficient teaching

The Organisation of Clinical Knowledge

This conception of the founders of our College and the means they took to make it operative are, I think, amongst the most valuable of our assets and perhaps like some other possessions, their real value is not fully appreciated until they are lost The underlying idea of our founders was that the realm of clinical knowledge was a subject worthy of the same treatment as that accorded to other branches of knowledge in a university, and that it demanded full equipment and organisation That is a position that has not always been conceded, nor even at the present day is it as universally recognised as it should be

There is sometimes an impression that what is called clinical research as well as clinical teaching is not of the standard or quality that justifies the use of such dignified words as those of research or teaching That, however, is perhaps rather a matter of the individual than of the subject Clinical research has in the past had followers of the greatest intellectual attainments men who by their discoveries in clinical medicine have permanently influenced medicine—for example, Sydenham in the seventeenth century and Hughlings Jackson in our own The teaching of clinical medicine calls also for special qualities owing to the intrinsic difficulties of the subject arising, partly from its complexity and largely from the fact that the material is that of suffering human beings The teaching of most subjects of any university curriculum does not present the difficulties that beset any clinical teacher who is desirous of treating his subject with scientific method and accuracy

Although I have emphasised, perhaps at too great length, these developments in clinical teaching, after all the greatest thing our founders did was to place the teaching of each subject in the medical curriculum in the charge of an expert in that branch and thus ensure that the subject should be envisaged from a broad and not from a narrow and purely utilitarian point of view That is a conception that has persisted for the 100 years that have elapsed and has slowly spread from here to every medical school in the country and has I hope, affected the outlook of every student of medicine that has passed through its halls We know that it has been successful in producing during the last 100 years a number of men who have, thanks largely to the inspiration they received from the ideals of their teachers, enlarged the boundaries of human knowledge

Scientific Method in the Teaching of Medicine

It is difficult to lay too much stress on the effect of such a policy in the case of such subjects as anatomy physiology, and the biological, chemical, and physical sciences ancillary to medicine Medicine itself is such a complex study that it is by no means well suited for the training of the average individual in what we may call for simplicity, scientific method Great men with gifts may achieve results of the first importance in medicine by their researches and yet never have received any special scientific training There have been many such, but this will not be the common lot, and for the multitude it is essential that an adequate training in scientific method should be provided, and it is equally essential that the imagination should be stimulated by such training, and this is most likely to occur when the subject matter is dealt with by one devoted to its study for its own sake No doubt this method is liable from time to time to cause difficulties, owing to the well-known impossibility of getting a quart into a pint pot, but on the whole the advantages outweigh the drawbacks

Placing the teaching of these subjects in the hands of unquestioned authorities on them led to other developments that have brought about great changes in teaching, and for that matter, in examining The professors very early on instituted practical classes, there were practical classes in chemistry from the beginning of the life of the College, and as early as 1845 a second professor of chemistry under the title of professor of practical chemistry was appointed Sharpey, the great professor of physiology, instituted practical classes in histology, and in 1855 a separate teacher of practical physiology and histology was appointed and later on Michael Foster occupied this position until 1870

It is interesting to note that University College did not follow the requirements of the licensing bodies and institute practical classes after they had been made compulsory by such examining bodies, but rather that University College established the practical classes to render the teaching more efficient, and ensure that the student's knowledge was obtained first hand, and then the examining bodies followed suit and laid down regulations making such classes obligatory The history of the College in later years is somewhat similar, there have been occasions even in quite recent times when teachers have tried to instil in those controlling examinations the methods that should be adopted, and it would seem that this is really a sound and truly physiological method that has also the record of past successes in its favour The practical classes were not confined to subjects in which laboratories formed an integral part of the teaching equipment, they were also instituted in the routine teaching of clinical medicine and surgery, and classes were formed enabling every student to receive definite and systematised instruction in the physical signs of disease This was a most important development inasmuch as it introduced scientific method in the teaching of the art of diagnosis of disease, and some of the most distinguished of the physicians of University College Hospital have been noted for their work in this branch of medicine Here I may mention two names, first that of Elliotson, who was a pioneer in introducing the stethoscope in this country, and Walshe, who by his work, his writings, and his teaching placed the study of the physical signs of disease on the secure basis that has been maintained ever since Walshe, through his pupils, carried the teaching of physical signs to more than one of the great medical schools of London Thus the teaching of medicine was rapidly put on the same level as that of the teaching of other branches of science, it was organised, systematised, and made objective and real, the student being made to realise facts for himself and not merely listen to *ex cathedra* utterances

There was another far-reaching development initiated in this College by the foundation of the chair of pathological anatomy in 1828, and although our founders held the view that the art of medicine must be founded on the study of morbid anatomy, it was not until 1872 that this subject became a compulsory one in the medical curriculum Here, however, in season and out of season, from the foundation of the College to the present day, all the teaching of medicine has been correlated with the teaching of morbid anatomy, and our belief and tradition have always been that this is essential for the progress of medicine as a science Our greatest teachers, like Walshe and Jenner, were insistent on this, and much of the success of our students in research, in teaching, and in the practice of their profession, is, to my mind, dependent on this method of training that is a stern corrective of fanciful and theoretical medicine that at all periods, including the present day, has its exponents who do not usually hide their lights under a bushel, and to whom the close association of the art of medicine with the facts of the dead-house is only a subject for cheap witticism

The Student's Opportunity

Another element that has had a great influence in the history of this College in all faculties, and not least in the Faculty of Medicine, is the fact that teachers have always recognised that one of their main duties is to enlarge the boundaries of knowledge and do all in their power to stimulate research Some have done this by their own work, others have achieved great results by the inspiring of their pupils but all have necessarily produced incalculable results in modifying the outlook and point of view of every intelligent student who has come under their influence I do not propose to attempt even to sketch what has been done in this direction in the past 100 years, all I desire to draw attention to is that so great was this influence that there have been many teachers here from the days of Sharpey and Wharton Jones to recent times, who have so inspired their pupils that these, even during their student career, have embarked on researches that have proved to be of permanent value The early histological and physiological researches of Lister are a sufficient illustration of this fact, and such facts form one of our most valuable traditions

In conclusion, I would desire to allude to other changes profoundly affecting the medical student that were initiated here either by our founders or by their early successors A hundred years ago the student was in a measure the appanage of some individual member of the hospital staff, in order to obtain the advantages of following his practice in the wards of the hospital he had to become his pupil and pay him personally a fee Later, when resident appointments were instituted, house physicians, house surgeons were personal appointments by the physician or surgeon concerned, and here, again, a fee was payable All such methods were swept away here and all appointments were made on the ground of merit alone, and no fees of this kind were received by the staff When we remember the great value of these appointments to the student, there is probably no appointment to a young man of such value as a house physiciancy or surgeoncy, and when we remember the extremely important part these officers play in the life of a teaching hospital it is perhaps unnecessary to dwell on the great effects that such a change as that made here in our early life must have had on medical education, at any rate, our example has been followed by others

The teaching of medicine is no light task, but so long as our teachers here are inspired by the same ideals as those that spurred on our founders. and so long as they faithfully follow them there is every reason to hope that with the enormously improved equipment of the present the successes of the future may be even greater than those of the past

---

MEDICINE AND THE LAW

Vaccination Register. Landlord's Right to Inspect

An unusual point of vaccination law came before the King's Bench Division at the beginning of this month The governors of the Peabody Donation Fund, incorporated by Royal Charter in 1900, own blocks of working-class dwellings in various parts of London and are authorised to impose regulations terms, and conditions on the occupation thereof The governors have made it a condition of every tenancy granted by them that every member of the tenant's family should be vaccinated In order to find out whether the condition was being obeyed, the superintendent of the Peabody estate at Southwark asked to be allowed to inspect the vaccination registers but was refused permission by the Southwark guardians The point had previously arisen in 1913 when a tenant made a statutory declaration of conscientious objection On that occasion the vaccination officer informed the superintendent of the Peabody buildings and the tenant was consequently given notice to quit The tenant thereupon complained to the President of the Local Government Board (the predecessor of the Minister of Health) who seems to have expressed the opinion that the vaccination officer had exceeded his duties Acting on this opinion the Southwark guardians refused the information in the present case, being themselves inclined to the view that it was not proper to allow the vaccination register to be searched for the purpose of putting pressure upon a tenant They at the same time expressed their desire to carry out the law and to act in any manner which the court might direct

The law is to be found in Section 24 of the Vaccination Act of 1867, which says that every registrar must keep a book in which he shall enter minutes of the notices of vaccination given by him and shall also register the certificates transmitted to him, the section declares that he is to allow searches to be made at a specified fee This seems clear enough and the only way in which the Southwark guardians could suggest that the right of inspecting the register had been taken away was by arguing that, because by later enactments the form of the register has been changed or extended therefore Section 24 has been impliedly repealed It is true that Section 2 of the 1898 Act provided that a parent might exempt himself from penalty by delivering to the vaccination officer a certificate of conscientious objection, and that this provision was further altered in 1907, so that the conscientious objector need merely send a statutory declaration instead of a magisterial certificate But as Lord Hewart has now observed, the original section of the 1867 Act remains substantially undisturbed The certificate of successful vaccination—the foundation of the section—remains; the other certificates as to unfitness for vaccination and insusceptibility to vaccination also stand, and the name of the medical practitioner is preserved as it always was The only new ingredient was the 1898 provision relating to conscientious objection, and it was a desperate argument to suggest that this had so altered the 1867 Act as impliedly to repeal Section 24 The three judges forming the court unanimously upheld the right of inspection and made absolute a rule *nisi* for *mandamus* directing the vaccination officer or officers of the Southwark guardians to show case why search of the register should not be allowed

Nuisance from Noise

Two motions for injunction to restrain nuisance from noise in London came before the Chancery Division on May 6th In one case the Strand Hotel Ltd applied to stop the use of a pneumatic drill in excavation operations on the site of Oddenino s Restaurant between 9 P M and 7 30 A M The action was settled on the terms of the injunction applied for except that the hour of 9 P M was altered to 10 P M · the motion was treated (as often happens in the Chancery Division) as the trial of the action and there was no order as to costs In the other case the Duke of Westminster applied for an injunction to restrain a defendant from leaving motor-cars (or permitting them to be left) standing in mews near Belgrave-square with engines running, from blowing horns or hooters without reasonable cause, and from doing any other thing which might cause nuisance, damage. inconvenience or disturbance to tenants and occupiers of adjacent properties The defendant was a sublessee of premises used as a motor garage with living rooms above, the subdemise contained the usual covenant against anything which might cause nuisance. inconvenience, &c, to the neighbours. Seven adjoining occupiers had complained it was said that people arrived at the premises at early hours in the morning and allowed their car engines to race noisily Mr Justice Clauson granted an injunction until trial of the action

Nuisance from noise is a matter in which hospitals and nursing-homes have a keen interest Although the noise of railways and trams the ordinary roar of traffic and the established sounds which assail the ear in an industrial district may have to be borne without remedy, the law will give some protection against the use at night of imported nuisances such as the pneumatic drill

Sale of Dentist s Practice. Allegation of Fraud

For the second time the jury have disagreed in the action brought by Mr Mervyn A Holland, of Upper Brook-street against Mr Cameron R. Stewart of St Andrew s-road, Surbiton for alleged fraudulent representation on the sale of a dental practice The plaintiff is thus at liberty to bring his action a third time During the course of the recent hearing the plaintiff was questioned as to the scale of his charges "What scale do you charge King s Counsel?" asked Mr Justice McCardie "It is what they are charging me that is worrying me, my lord" replied the plaintiff One need hardly point out that cases of this kind suggest that some method of arbitration would be more satisfactory, and would more easily avoid undesirable publicity and obtain the desired finality as well as being less expensive than protracted and inconclusive hearings before a judge and jury

The case for the plaintiff was shortly that the defendant told him the practice was capable of producing £2000 a year that he therefore bought it for £2000 and eventually found that the total value of the patients who came to him from the plaintiff was less than £900 It was suggested that some of the names on the books were those of patients who had consulted Mr Stewart as long ago as 190 and then only once, and that other names were those of members of the Canadian Expeditionary Force who returned to their own country after the war The *case for the defendant* was a denial of misrepresentation, he maintained that whatever he told Mr Holland was true or that he (Mr Stewart) believed it to be true · he contended that Mr Holland relied on the reports of his accountants who had examined the books of the practice The defendant, in answer to the judge, said the plaintiff had never asked him to specify the number of "live" patients in the practice; he added that no man on earth could pin himself down to a definite figure in this connexion. On the third day of the present hearing the jury, after retiring for over two hours, said they found a verdict for the plaintiff and assessed the damages at one farthing. The judge pointed out that this would hardly do; if there was any damage at all, it was indisputable that the amount of damages must be substantial. After his lordship had explained the law again to the jury, a juryman stated that they had reached their verdict in the endeavour to avoid placing on Mr. Stewart the stigma of fraud and in order to come to a final decision. Asked if the jury would like to retire again, a juror replied that further discussion was useless. "A number of us" he said, "object to finding that the defendant intentionally acted fraudulently; we believe that this practice was arranged to be bought in some private conversation between the plaintiff and the defendant which has not been disclosed in court because it was under the seal or secrecy of freemasonry." Whatever the justification for this unusual comment, the jury were held to have disagreed and they were, therefore, discharged. The defendant has the satisfaction of knowing that on the allegation of fraud (which every professional man must resist with his last penny) the jury were not prepared to find against him; but he has the uncomfortable uncertainty of not knowing whether these protracted proceedings will again be renewed.

PHYSIOLOGICAL SOCIETY

THE JUBILEE DINNER

THE jubilee dinner of this Society, held on Friday evening May 13th, at the Hotel Metropole, London, under the chairmanship of Sir **EDWARD SHARPEY-SCHAFER**, was a highly successful function. The proceedings were prolonged till the approach of midnight, and the speeches, if discursive, were informing as to the growth of the science, from its infancy in Victorian days to its present proud position.

After the loyal toasts the prosperity of the Society was proposed by Major **WALTER ELLIOT**, M.P., D.Sc., who rapidly traced its growth through 50 years of steady evolution, recalling to memory, among the famous men of old, Sharpey, Pye-Smith, Dew Smith, Burdon-Sanderson, Michael Foster, and David Ferrier, Thiselton-Dyer, Ray Lankester, and the Chairman himself, four among the pioneers who still were with us. And with them he coupled Lord Balfour, the President of the Council, as of similar philosophic attainments. Speaking as one who had left the Arcadian paths of science and declined into Parliamentary life, he painted the joys of those who were privileged to be working for the revelation of secrets whose wonders were certainly to surpass the wonders already laid bare, as the apparently logical framework of the past was upset by modern objectives.

Sir **EDWARD SHARPEY-SCHAFER**, in reply, pointed to the history of the Society and the character of the present meeting as proof that the aims of a small dining club, founded in 1876, had had a wonderful fulfilment. The club had been started by a group of biologists in order to defend their studies against the attacks of ignorant humanitarians, which were resulting in giving to France and Germany a clear pre-eminence over British scientists. The first forward movement in physiological education came, he said, from Burdon-Sanderson, a physician, and Sharpey at University College, London, assisted by Michael Foster, a young man imported from general practice in Huntingdon. Then came Humphry at Cambridge, an anatomist who recognised the sterility of anatomy uninformed by biology. The dinner meetings, from which the Physiological Society took its origin, were organised by Burdon-Sanderson, and the club was at first limited to the 19 persons who responded to some 40 invitations, of whom, as they had been told four still survived. From this movement, designed to further physiological research and to enter into international relations for that purpose, the Physiological Society had sprung.

The guests were proposed by Sir **CHARLES SHERRINGTON**, who welcomed especially the visitors from abroad, and hoped they would not be disappointed at receiving a more material welcome than would have been represented by physiological papers. He coupled with the toast the names of Sir Ernest Rutherford, President of the Royal Society, Prof. Giulio Fano, from Rome, Prof. E. Gley, from Paris, and Viscount Knutsford, Chairman of the Research Defence Society.

Sir **ERNEST RUTHERFORD** said that the Physiological Society could be claimed as a child of the Royal Society, its founders and its eminent workers being almost without exception Fellows of the parent Association. Speaking as a physicist, he pointed to the multiplying and strengthening of the links between the two branches of knowledge as instanced by the researches, for example, of A. V. Hill, Einthoven, and Adrian, and said that such cooperation was leading to great developments in biological knowledge, and in future would produce even vaster results. Like the previous speakers he paid tribute to the loss recently sustained by science in the death of Starling.

Prof. **FANO** paid a tribute to England in terms which were warmly received. He spoke of English work not only at home but in our many colonies which he had visited, and showed himself a diligent follower of English literature as well as English science in his love of Dickens, Thackeray, Eliot, and Conrad, the Pole. He compared Dante, the great artist, with Shakespeare, the world's philosopher, some of whose supreme heroines were Italian women.

Prof. **GLEY** spoke warmly of the debt owed by all to English physiology for its accomplishments during the past half century. He recalled to the audience the loss sustained by the world through the untimely death of Victor Horsley, and concluded by an eloquent declaration that physiology was a truly international matter, and that all over the world those who sought out its truths did so upon common principles.

Lord **KNUTSFORD** spoke in unconventional vein. Reminded by a personal swimming incident, he called the attention of the meeting to the debt owing to the Chairman for his work in devising the technique for the restoration of the apparently drowned. He declared that he knew no hole except a golf hole, that a physiologist could not get out of, and he wished that the House of Lords could receive the counsel of some physiologists as peers. He regretted, speaking for the Research Defence Society, that more medical men did not combine to refute the calumnies of the enemies of research.

The health of the Chairman was proposed by Dr. **LEONARD HILL**, and after a brief response from the chair, the evening closed with the singing of Auld Lang Syne.

KING EDWARD'S HOSPITAL FUND FOR LONDON

THE annual meeting of this Fund was held at St. James's Palace on May 13th. The **PRINCE OF WALES** (the President), who was in the chair, read a message from the King expressing appreciation for the work being done. The Prince of Wales went on to say that the ordinary distribution had been growing steadily since the Fund was founded 30 years ago by King Edward. In 1926, as in 1925, it amounted to £245,000 and to keep it at this figure at least £27,000 was needed in donations alone. Last year £17,000 had been received in two gifts of £10,000 and £7000, and this year one of the two donors, who for the fifth time preferred to be anonymous, had given £8000. Very nearly the whole of the Wells legacies (more than £200,000) had now been distributed and these legacies had helped with 50 schemes, providing about 1200 additional beds, of which 144 were beds for accidents This was the second time the King's Fund had had a large sum of money at its disposal for helping the hospitals with schemes of extension and improvement In 1920 £250,000 was entrusted to the Fund for that purpose by the Joint Committee of the British Red Cross Society and the Order of St John out of surplus war funds Then, in 1924, munificent legacies were received from Mr and Mrs Wells The need for hospital extensions was so great that the Red Cross money had been spent, and numbers of fresh schemes had come forward Now, after another three years, the Wells legacies were practically exhausted, and still fresh schemes came on It was his urgent desire that other generous donors, when they saw the enormous good done by the use of the Wells gifts, would be forthcoming to enable them to meet the new needs that were already in sight It was really astonishing what a lot of money was subscribed under the voluntary system for hospital building schemes The total in 1925 was no less than £691,000 Part of this was given in large sums by public-spirited individuals who became personally interested in the schemes of particular hospitals Part of it came from gifts entrusted to the King's Fund to be distributed according to the knowledge which the Central Fund possessed of the relative claims of the different hospitals The pensions scheme was an example of another function of a central fund Assistance had been offered to the hospitals in London that had decided to adopt the scheme The King's Fund would not itself take part in the administration, but gave the scheme its blessing and its help, believing it to be in the interests of the efficiency of the hospitals and the nursing service of the country. Just now the question of the provision of hospital accommodation for paying patients had come very much to the front, and he had appointed a committee of inquiry to go into the subject with Lord Hambleden as chairman, who would have as his committee two medical members Sir John Rose Bradford and Mr Warren Low, and two lay members, Sir Bernard Mallet and Prof Winifred Cullis

Lord **REVELSTOKE** (the hon treasurer) said that the accounts showing the results of the year's working were rather better than had been anticipated, for the net receipts exceeded the estimates by nearly £5000 The receipts less expenses amounted to just over £240,000, while the amount of the ordinary distribution was £245,000 Further, the Fund distributed an additional £39,750 on account of the Wells legacies The total amount distributed was therefore £284,750 During the 30 years since the King's Fund was founded it had distributed in all a total of somewhat over £5,500,000 The position of the invested funds was satisfactory The market value of the investments on Dec 31st last, £3,369,242, was now 3 1 per cent below their book value—a very satisfactory result in view of the fact that a proportion of the securities was acquired more than 20 years ago, when the rates of interest ruling were extremely low

On the motion of the Earl of **DONOUGHMORE** (chairman of the Management Committee), seconded by Sir **BERKELEY MOYNIHAN**, the annual report was adopted, and after a vote of thanks to the Prince of Wales, the proceedings ended

---

LONDON HOSPITAL SATURDAY FUND —The report for 1926 states that the income of the general fund was £79,192, almost the whole of which was derived from collections and donations The income was somewhat reduced by the industrial unrest, and the present year already shows an increase upon the corresponding period of 1926

WEST END HOSPITAL FOR NERVOUS DISEASES —Speaking at the annual meeting of governors of this hospital, Lord Lascelles said that of the 317 patients who were admitted to the wards last year, 107 were cured and 113 relieved, only 77 showed no improvement He expressed the hope that the institution would receive the means to undertake a thorough survey of the many mysterious and dangerous maladies connected with the nervous system

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Housing in Glasgow

I **WONDER** if any English town can show, on any serious scale, a parallel to the Glasgow " backlands " (This term is locally pronounced as if it were two words each of equal accent) A typical example is a four or five-story tenement facing the street with another similar tenement built perhaps 20 feet behind it The backland is approached through passages in the front blocks, the lower floors can never get direct sunlight and many of the rooms require artificial light all day The rapacity of the early builders was uncontrolled by the municipality or Government, and the population of Glasgow increased so rapidly that its housing and rehousing now present a gigantic problem At a summer school of social study held on the Gareloch, Dr A S MacGregor the medical officer of health for the city, said that in a group of streets recently surveyed 14 per cent of the two-apartment houses were found to be harbouring two families Some 3000 houses have been scheduled for demolition and the destruction of another 1000 is under consideration in view of their congestion dilapidation, or dampness In the older houses, especially in the east end of Glasgow, damp is very common

At a recent official inquiry Dr MacGregor stated that he had carefully studied the vital statistics of two of the scheduled areas He found that, while the city death-rate was 14 8 per 1000, the Coalhill district death-rate was 24 7, and the Rumford-street death-rate 24 5 For the city as a whole the respiratory death-rate was 2 7, for those two districts it was 6 For the city as a whole the infantile death-rate was 107 per 1000 births, for Coalhill-street it was 174, for Rumford-street, 138 In Glasgow the populations at risk in these areas are large enough to give a high value to those death-rates Usually, when such figures are adduced to justify a slum clearance scheme, the quantities are too small to be significant But Glasgow can show a long series of these housing-health studies, and the cumulative effect of the figures is strongly in favour of the view that the incidence of death and disease is a real function of overcrowding It has been held that the lower class of house attracts the feebler class of population and that the high death-rates associated with overcrowding are not due to mere aggregation but to natural selection of the weaker stocks It is difficult, however, to accept this comfortable doctrine

One fact brought forward by Dr A K Chalmers, the late medical officer of health for the city, seems never to have been adequately investigated—namely, that the populations of one-room, two-room, and three-room houses are in a state of perpetual flow up *and* down There is not a constant population in any one class of house Yet it is found that the leading death-rates and disease-rates vary inversely as the number of rooms In an over-crowded hospital ward we invariably get an increase of evil results due to mere aggregation for with overcrowding the " other conditions " necessarily change It is not unreasonable to expect the same ill-effects in over-crowded smaller houses where the hygienic conditions are almost always bad, especially in a great city. The problem is not one to be too dogmatic about, but I should expect medical officers of health generally to support the views implied in Dr MacGregor's evidence

Detection of Anthrax

An important practical point has been raised at the Aberdeen County Council In Scotland the English Board of Agriculture controls the contagious diseases of animals It was said that of three cases of suspected anthrax in animals diagnosed by a local veterinary surgeon two had not been confirmed by the Ministry of Agriculture's experts Insurance companies only paid on the verdict of the Ministry and, therefore, great hardship was inflicted on farmers if the local veterinary surgeon said an animal died of anthrax and the Ministry denied it. It was agreed that in future swabs be sent to the local authority's veterinary inspector. Whilst no time must be lost in investigating a case of anthrax, it should be possible to make arrangements both for local diagnosis and central confirmation where necessary.

Official Recognition of Research

It is worth noting that, during his research on spirochætal jaundice,[1] Dr. George Buchanan, in order to get direct access to his material, was appointed a Commissioner by the Scottish Board of Health, with power to make the necessary inquiries on the spot along with a medical officer of the Board. This is a good instance of how the work of the Medical Research Council's investigators can be correlated with administrative organisations.

The Empire Marketing Board has made a special grant of £2850 for the investigation of the food value of milk. An elaborate experiment is now going on under the direction of the Rowett Institute, Aberdeen, and a report will doubtless be published later in the year.

There is a good deal of discussion about the venereal diseases clauses in the Edinburgh Bill. The problem of how best to secure continued treatment is still unsolved. All that we can say at the moment is that the Edinburgh V.D. Department is one of the most successful in the country.

IRELAND

(FROM OUR OWN CORRESPONDENT.)

Medical Registration in the Free State

THE Medical Practitioners Bill passed through all its stages in the Dail last week, and will probably have been finally dealt with by the Senate this week. Mr. McGilligan, the Minister in charge, moved two amendments which improved the Bill. He met the case that had been made to him on behalf of the two Royal Colleges, and agreed to give them separate representation on the Medical Council. He also provided that a casual vacancy in the direct representation should be filled by election and not by cooption. Mr. T. Hennessy moved an amendment to increase the number of direct representatives on the Council from two to four. The Minister was unwilling to accept this, but stated that the nominees of the Executive Council would be representative of the profession. Mr. Hennessy's amendment was withdrawn and the Minister carried a fresh amendment increasing the number of nominees of the Executive Council from one to two.

There was some discussion in the Dail about the anomalous position produced by giving separate representation on the Council to the several constituent colleges of the National University, while leaving the University itself unrepresented, but the Bill has gone through without change in this respect. It is unfortunate that there was not more time for consideration in the Dail, and it is hoped that the Senate may be able to do something to clear up an illogical position which, if left uncorrected, may hamper the working of the Council. As the Bill now stands, the constitution of the Council is based on two apparently incompatible principles—namely, representation of licensing bodies, applied in the case of Dublin University, the two Royal Colleges, and the Apothecaries Hall; and representation of teaching bodies, applied in the case of the university colleges at Dublin, Cork, and Galway. Under later sections of the Bill the Council is empowered to report to the Executive Council on the inadequacy of examinations and on the inadequacy of courses of study. The Executive Council, on consideration of such report, may, if it think fit, order that such examination shall cease to be a qualifying examination, so that the college or body which is responsible for an inadequate course of study loses its right to grant a qualifying diploma. In the former instance the body subjected to such order shall, for the time being, lose its right to representation on the Council. It is difficult to see in what way these clauses apply to the constituent colleges of the National University. As they do not grant diplomas they cannot be penalised by the suspension of that power, and at any rate their right of sending representatives to the Council remains. If they offend the National University will be punished. One of these constituent colleges, that of Galway, is reported to have had only two entrants as medical students last winter session. It is clear that with so small an entry the continued existence of the school is in some doubt. It seems, however, that, even if the Galway school of medicine were closed, the College of Galway would, in the absence of further legislation, continue to send its representative to the Medical Council.

Registration of Dentists

The Dentists Bill, 1927, was introduced to the Dail last week, but the President has announced that it is not his intention to press it in the present session. It follows fairly closely the lines of the Medical Practitioners Bill, in providing for the establishment of a Free State Dental Board and the maintenance of a Dentists Register. The relations of the Free State Dental Board to the [British] Dental Board, and of the Free State Register to the Dentists Register, appear to be parallel to those set up in the medical sphere. The Free State Dental Board is to consist of nine members, appointed as follows: One by the Executive Council, three by the Medical Council, one by the persons in the Free State registered under Section 3 of the Dentists Act of 1921, and four by dentists in the Free State otherwise registered. The Board is concerned with registration and discipline only, and does not appear to have any concern with education. Moreover, it only inquires into charges of infamous or disgraceful conduct when these charges are brought before it by a university or college having power to grant licences to practise dentistry. The right of medical men on the Register at the date of passing of the Act to practise dentistry is preserved, but future practitioners have their freedom curtailed. It is provided that Section 41, which contains a general prohibition of dental practice by persons not on the Dentists Register, shall not operate to prohibit—

> The performance of any surgical operation in connexion with the tissues of the mouth or jaws, or the giving of any dental treatment, advice, or attendance in urgent dental cases by any registered medical practitioner.

This clause is so ambiguous as to be dangerous, and in its meaning seems to be an unwarrantable interference with the privilege of medical men to practise any branch of medicine or surgery they think fit. It may be just as well that the Bill is not to be pressed at present, and that further time should be given for consideration.

BERLIN

(FROM OUR OWN CORRESPONDENT.)

The Press and the Medical Profession

THE daily papers are becoming more and more inclined to publish photographs of medical men whose names are for some reason or other before the public, and at a recent meeting the Berlin Medical Society protested against this practice on the ground that it savours of advertisement. A resolution was unanimously adopted, charging members of the society to do their utmost to prevent newspapers from publishing their photographs and professional records. On the other hand, the Association of the German Press, which represents all the leading papers in Germany, resolved at its last meeting that its members shall henceforward refuse to publish advertisements promising medical attendance by letter, advertisements guaranteeing cures for disease such as tuberculosis, cancer and tabes, and advertisements recommending cures by astrology and other metaphysical methods It will be a serious blow to quackery if the newspapers carry out this recommendation

---

[1] See THE LANCET, May 7th, p. 985.

Health of the German People.

In a report submitted to the Reichstag the Government states that the health of Germany has improved since 1924 The number of births has risen and the population is no longer decreasing In 1925 the live birth-rate was 20 6 per 1000, compared with 20 5 in 1924, it is unsatisfactory however to find that in the first nine months of 1926 in the larger cities for which reliable figures are already available, the rate was only 15 6 as against 16 4 in the same period in 1925 The general death-rate has fallen to 11 9 per 1000 being thus almost the smallest in Europe, but the infant mortality in Germany is much greater than in Denmark and Holland, the countries whose general death-rate is lowest Notwithstanding the housing shortage the mortality from tuberculosis has decreased in the larger towns During 1925 moreover, there were no epidemics of major importance The improvement in the public health is attributed to the arrangements for social relief and to the beneficial effect of sport

Surgery and Diabetes

Not long ago a paper dealing with operations upon diabetic patients was read by Dr Rosenberg before the Berlin Surgical Society Since the discovery of insulin he said, the mortality of these operations has decreased from 50 per cent to about 12 per cent The principal danger is from coma and infection In the Charlottenburg Hospital between 1919 and 1922 seven diabetic patients were operated on of whom three died from coma and one from septicæmia Between 1922 and 1926 operations were done on 35 diabetics and there were 11 deaths, six of the cases were dealt with in the early days of insulin, when the technique was not yet fully developed, but in the later ones there was not a single death from coma This good result was achieved by giving insulin in doses sufficient to remove sugar not only from the urine, but also (in excess) from the blood If preparation begins several days before operation the prognosis is hardly worse in diabetic than in normal subjects On the day of operation, and in the few days afterwards, it is necessary to give larger doses

Supply of Human Milk to Infants

In Magdeburg during the war the milk of mothers who had more than they needed was collected for the use of infants who were insufficiently fed The quantity of milk delivered was some 80 or 100 litres a month and the women were induced to deliver their milk by the offer of money and (what was then still more important to them) of food In 1922 the system had to be abandoned because of the financial condition of the country; but recently it has been reorganised in connexion with a maternity hospital A grant of M 5 per litre is made for the milk, whilst women of the better class who decline to accept money receive a certificate instead The daily quantity of milk sent in is about 3 litres

Hydrophobia in Germany

In 1924 2423 cases were reported in Germany of people being bitten by dogs suffering or suspected of suffering from rabies Of those bitten 41 developed rabies, as against 63 in the previous year Treatment at the Koch Institute in Berlin was given to 504 people, whilst 371 were dealt with at the Institute of Hygiene at Breslau Generally, cases of rabies are more frequent in the eastern provinces than in the west The death-rate of people treated at the above institute was 1 4 per cent in 1924 0 5 per cent in 1923 0 9 per cent in 1922 and 1 4 per cent in 1921 whilst for people who did not receive such treatment the death-rates were 8, 8 1, 10 2, and 7 3 per cent respectively

Nutrition and Fertility

The experience of the war suggests that nutrition has no influence on the incidence of multiple births The number of these births underwent no significant change between 1909 and 1921, which includes, of course, the period of starvation during the blockade, nor was any alteration observed in the general fertility although it is known that domestic animals whose food is supplied regularly reproduce themselves more quickly than wild animals of the same species

State Insurance in Germany

According to a statistical record of the German Insurance Office, 26,000,000 people in 1925 were compulsorily insured against accidents In 107 571 cases—7 per cent of which were fatal accidents—an insurance allowance was granted for the first time, the total amount being M 170 000,000 16 500,000 people were insured against sickness and old age and 200,000 pensions were granted for invalidity—apart from 50 000 allowances for widows and 40 000 for orphans The insurance offices themselves maintain 51 sanatoriums with 7161 beds for tuberculous patients and 47 sanatoriums with 5668 beds for other diseases Twenty million people are compulsory members of sick-clubs 9,500 000 cases of sickness being registered in 1925, compared with 7 500,000 in the year before The average duration of disability due to disease was 25 days in industrial and 23 days in agricultural workers

Agricultural Experiments with Iodine

The good results obtained with iodine in the prophylaxis and treatment of goitre have led to an attempt to increase the iodine-content of vegetable foods Experiments have been made at the agricultural institute of Hohenheim on the effects of adding iodide of potash to the Chile saltpetre used as a fertiliser but it has proved impossible to increase the amount of iodine in the plants intended for human consumption

New Light on the Death of Schiller

Dr Brauer states in an article in the *Zeitschrift fur Medizinische Chemie* that the death of the poet Friedrich Schiller was probably caused by a green wallpaper A piece of this wallpaper has recently been found and chemical examination shows that its colour was produced by Schweinfurt green a dye containing arsenic From correspondence between Schiller and Goethe it has been ascertained that it was Goethe who purchased the wallpaper for his friend and thus unwittingly caused his death In 1886 the use of Schweinfurt green for wallpapers was strictly prohibited in Germany

---

AUTUMN MEDICAL COURSES AT CARLSBAD —The ninth series of International Medical Courses will be held at Carlsbad from Sept 18th–24th and free visas will be granted on application to persons attending these courses either as students or lecturers The newly built carbonic acid gas bath which makes the sixth bathing establishment contains ten cabins and a general room for dry baths besides nine cabins and a general room for cold water treatments, as well as spacious roof platforms for sun and air bathing and rest cures

DONATIONS AND BEQUESTS —Mrs Dowthwaite, of Aberdovey has given £1000 to the building fund of the Dolgelley and Barmouth College Hospital —Miss Violet E. Wills has given £18 000 to build, equip, and endow a nursing home at Partis College, Bath, for aged and infirm members of the institution in memory of her mother, Lady Wills —Mr Frank Harrison a timber merchant of Boston, Lincolnshire has given £20 000 to the endowment fund of the Boston Hospital —Mr Joshua H. Hoyle of Todmorden, has given £1000 to the Yorkshire Council of the British Cancer Campaign —The late Mr Henry Folland of Swansea left among other bequests £10 000 to the Swansea General Hospital and £1000 to the Swansea Institution for the Blind.—By will the late Mr John Lindon, of Oxton, Birkenhead left £1000 to Birkenhead and Wirral Children s Hospital and £1000 to Birkenhead Borough Hospital, in each case for the endowment of beds bearing his name.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

OPTICAL PRACTITIONERS (REGISTRATION) BILL

MR WEST RUSSELL, in moving the second reading of the Optical Practitioners (Registration) Bill on Friday, May 13th, said that while there might be a considerable difference of opinion in regard to some of the details there were, he thought, few hon Members who were not in complete accord with the broad principle upon which the Bill was based He believed that this was the only country where there was *no* legislation for the registration of opticians It might be that as a result of that legislation the people of the United States of America were probably the most bespectacled people in the world That was not because the eyesight of the people in the United States was more deficient than that of the people of this country, but it was because the people of the United States had long since realised that good eyesight was of enormous national importance He thought he was right in saying that at the present moment in this country among adults as well as among children there were more spectacles worn than was the case some years ago, not because the eyesight of the people was worse, but largely on account of the voluntary efforts on the part of opticians to cope with the problem The same principle as that which was embodied in this Bill was also embodied in many Acts of Parliament dealing, for example, with dentists, nurses, and midwives The principle of State registers had been in operation in regard to other professions for a considerable time and had met with great success He thought that it would be agreed that the work of opticians and the effect of it on the welfare of the country was a matter of national importance It was said on good authority that at the present moment in this country something like 15,000,000 people, or about one-third of the population, were suffering from a measure of defective eyesight, and on statistics which he believed were vouched for there were in various industries some 1,000,000 people, suffering from short sight, disease of the eye, or some defect of eye construction, while in the report last year by the Board of Education it was stated that in that year alone something like 16,000 school-children were treated for squint It was also stated that something like 21 8 per cent of school-children suffered from defective sight Until recently extraordinarily little was done to cope with this problem, and what had been done had been accomplished through the voluntary enterprise of the present Opticians' Council Under that Council, and the Council of the Worshipful Company of Spectacle Makers, they had a registration of something like 3500 opticians of whose qualifications some guarantee was given The course of training prescribed by the Council was very severe indeed It was a training which enabled opticians not only to test the eye and to provide the spectacles that were necessary, but it also equipped opticians with a knowledge of the construction of the eye, and of the matters pertaining to it

Ophthalmic Benefit

There was another aspect of this question which was of very great importance Under National Health Insurance there was what was known as ophthalmic benefit In 1923 when it was first provided the position of the approved societies was very perplexing There was no one to administer it and it was at that time that the Joint Council of Qualified Opticians was brought into being Through that Council the approved societies were provided with qualified men who were able to carry out the work of administering this benefit In 1923 something like £3000 was spent on ophthalmic benefit, in 1924, £17,000, in 1925, £24,000, and in October, 1926, there had been spent something like £63,000 This was a discretionary and not a statutory benefit, and one over which the Minister of Health had no control whatever In the first five years of the National Health Insurance the surplus for distribution as ophthalmic benefit was something like £32,000 a year There had been a second valuation and according to that there was a distribution of something like £420,000, which, taken over five years, amounted to a sum of £2,000,000 to be distributed for ophthalmic benefit At the moment there was no real authority established by law for the control and direction of this large sum, but sooner or later some body, such as it was hoped would be created under this Bill, would be brought in to coöperate with the Ministry of Health in the distribution of this ophthalmic benefit The object of this Bill was to register qualified opticians There was already a very complete voluntary register and the Council already exercised very considerable disciplinary powers, but its work would be infinitely more effective if a status was given to opticians similar to that which had been given to dentists and others There were a large number of quacks and vendors of spectacles who had neither the apparatus nor the ability to test sight, and naturally there was something of a vested interest there which would be affected by this Bill There were also a large number of opticians who were not qualified, but who had had a long experience of this kind of work They might have difficulty in satisfying the examination tests, but there was nothing in the Bill to prevent anyone who was carrying on the work of an optician from doing so All it would do was to enable the public to distinguish between men whose qualifications were guaranteed by a responsible body, and those whose qualifications could not be vouched for Power was given to this body to consider each case on its merits, and though certain unregistered opticians might not be able to pass the necessary examinations it was not by examination alone that their claim for registration would be decided While the Bill would tend to eliminate all quacks and mere sellers of spectacles, who constituted a very considerable danger, it would at the same time create and register a body of men with a standard of qualifications and able to give a guarantee to the general public that they were able to carry out such work as sight-testing and spectacle-making

Opposition to the Bill by Doctors

The most serious opposition to the Bill came, as one would expect, from the medical authorities Their opposition, as he understood it, was that a Bill of this kind would give to opticians a status that would rather suggest to the general public that the registered optician was capable and qualified to deal with all matters concerning the eyes Defective eyesight came under various heads First, there was the defect due to something in the construction of the eye, and that could readily be remedied by the provision of glasses Secondly, there was the defect due to some disease or trouble not centred in the eye at all, but somewhere in the constitution of the individual But the curious thing was that of this defective eyesight 95 per cent, it was said, was due entirely to error of refraction arising from some construction of the eye, and only 5 per cent was due to some disease or other cause The medical authorities, as he understood it, contended that the danger within that 5 per cent was so great that while they might have a highly qualified optician able to test the eyes and prepare a prescription for glasses, and to provide the glasses, he would not have the training necessary to enable him to diagnose any trouble that might arise either from disease of the eye or other weakness in the constitution While it was true that an optician might not be able to diagnose disease of the eye or the source of eye trouble, his training would enable him to detect it and to realise the cases that ought to be dealt with not merely by the provision of spectacles but ought to be passed on to some medical authority Hon Members must bear in mind that at the present moment a great deal of this work was being done by opticians and not by medical practitioners He quite realised that in moving the second reading of this Bill the promoters were in some difficulty There was a Departmental Committee sitting to inquire into the merits of this Bill But he thought it would be a mistake if the time that was devoted to the second reading was altogether lost He hoped that by the time this Bill reached the Committee stage the Departmental Committee would have reported

Organisations Supporting the Bill

MR ROY BIRD seconded the motion for the second reading of the Bill He said there were two organisations interested in the promotion of this Bill These were the British Optical Association and the Worshipful Company of Spectacle Makers The latter, which was one of the ancient City Guilds, had specialised in teaching their members and those who were not necessarily liverymen of that company the practice of optics These two organisations had joined together to form the Joint Council of Qualified Optical Practitioners The number of members registered under that body was well over 3000 On the other hand, the number of medical men who appeared on the register of the British Medical Association as ophthalmic surgeons, or as possessing some special qualifications to deal with the eyes, was only 700 That number had to be subdivided, because only about 25 per cent could really be described as ophthalmic surgeons Fifty per cent on the list were members of the medical profession who did not specialise in the treatment of diseases of the eye, but who had at some time held an appointment, or possibly written a paper, dealing with the eyes The remaining 25 per cent had no special qualification to deal with the eyes, or none which was shown in the Medical Register The medical profession claimed that 700 men could deal with the care of the eyesight of the whole of the population of this country Some very interesting figures were given during the inquiry of the Royal Commission on National Health Insurance as to the distribution of medical men over England In 558 towns there were only 397 qualified ophthalmic surgeons practising If they took ten towns in the list which were health resorts and ten towns which were industrial centres they found that there was a very small number of ophthalmic surgeons in the industrial centres and that they were congregated either in the West End of London or in the big provincial towns, or in famous health resorts Therefore, it was impossible to claim that the members of the medical profession who were qualified as ophthalmic surgeons could look after the whole community In a great many towns there was no ophthalmic surgeon at all but there were qualified opticians and he submitted that that was a very material consideration to bear in mind when they were considering what should be done in this matter

An Amendment

Dr VERNON DAVIES moved the following amendment "That this House declines to give a second reading to a Bill the subject matter of which is at the present time being investigated by a Departmental Committee" He said that he and the hon Members associated with him desired to show the House how in their opinion this was a bad Bill, and one which it would be impossible to work. In recent years there had been rather an epidemic of applications for registration by organisations or societies of practitioners He found from information that had been given to him that the Joint Council of Qualified Opticians consisted of a little over 3000 members Yet there were 30,000 persons in the United Kingdom who obtained the whole or part their living from practice as oculists He found that the organisations which held examinations and granted certificates were the College of Opticians, the National Association of Opticians, the Institute of Chemist Opticians, and the Joint Council of Qualified Opticians The Institute of Chemist Opticians very unfortunately or presumptuously said that the Joint Council of Qualified Opticians had no right to speak for the rest of the profession. They even went so far as to say that they themselves were the only qualified people by statute among the lot and the only people who had passed a statutory examination

Mr ROY BIRD The National Association of Opticians are supporting the Bill

Dr DAVIES said he had so far referred to only one organisation who disapproved of the Bill—namely, the Institute of Chemist Opticians They were 5000 in number But they had to look at the matter more or less from the point of view of public utility Was there a need for a Bill for the registration of opticians, and, if so, were these the proper people to bring the proposals forward, and was it in the public interest? He had indicated that the promoters of the Bill had not the unanimous approval of the profession They had not been able to get very much information that day as to what the qualifications of these gentlemen really were, or who decided as to the standard of the examinations An ophthalmic surgeon of very long experience had remarked to him that he had never in the course of his professional life known any patient go into a spectacle shop and come out without spectacles The medical profession had adopted a very definite attitude on this subject They contended that the eye was an important organ, that training for the treatment of eye diseases called for special and prolonged study, and that even when a man was qualified, if he wished to qualify as an eye surgeon he ought, after qualifying, to undertake special work in connexion with the eye

Mr H WILLIAMS How long does the ordinary medical student devote to the study of the eye?

Dr DAVIES said that speaking from memory the medical student attended a course of lectures, and in his time they had to make 30 practical attendances at the hospital He (Dr Davies) did not practise as an ophthalmic surgeon. To do that he would have been compelled after graduation to take a special course in the eye and would have had to hold a position as house surgeon in an eye hospital It would be found that practically all the ophthalmic surgeons in this country had had extended post-graduate training in that capacity It was said that this Bill would do little more than regularise what was the present practice He differed from that A body of unqualified men with a certain amount of training, which might be limited or otherwise, were asking for State approval of their profession by the grant of registration If they were successful the public would believe that because they had received the approval of Parliament they must be competent to examine and treat eyes That was a position which could not be maintained He found that one college gave its degree or diploma for 50 hospital attendances, of which 25 at least must be devoted to the anatomy, physiology and pathology of the eye These three important subjects had to be learned in 25 lectures Medical men said that that was an absolute impossibility, no matter how clever the student or how expert the lecturer

Mr COVE Is not one of the purposes of establishing registration to improve the qualifications of these people and generally to raise the standard?

Dr DAVIES said that was possibly so, and if a Bill were produced which merely set out definitely what the qualifications and training were to be it would have an additional claim on the attention of the House, but this Bill was vague and impracticable The suggested Board was to consist of 12 members, one of whom was to be nominated by the General Medical Council He did not think for a moment that the General Medical Council would nominate a member, as it would be outside their jurisdiction. Eight members were to be members of various optical societies, probably chosen by this joint board, but not giving any of the other organisations the right to be included In two or three years probably the whole registration would get into the hands of this small joint council to the detriment of the rest of the profession They knew that it had been the practice for a long time for most patients to go to opticians to have their eyes tested, and he believed that 90 per cent of the eyes examined had no disease at all It might, however, happen among the remaining small percentage that spectacles would be given to a man, or a drug would be put in his eye, which would do irreparable damage The importance of the matter was increased by the fact that optical benefits were given by the approved societies, and the Minister of Health had to be certain that insured persons were getting efficient optical benefits with a minimum of danger The great difficulty had been the shortage of ophthalmic surgeons and the very high fees charged which few insured persons could afford The House might devote attention to the point whether there was any scheme whereby the claims of the doctors and of the opticians could be met He said at once that if the opticians were satisfied with the purely refractive work there would not be a word to say against it; but the difficulty was that they claimed to be able to detect disease and to send on any case of disease for medical treatment But the question was whether they would send on such cases Sir George Berry, who would second the amendment, was an expert ophthalmic surgeon and he would probably tell the House from the medical point of view of the many dangers which were inherent in the present Bill

The Medical Point of View

SIR GEORGE BERRY said he seconded the amendment not because he had any personal interest in the matter, or any axe to grind, but because he was convinced that legislation on the lines proposed in the Bill would not be in the interests of the public He admitted at once that there was no reason why the public should not be assured of the services of properly qualified opticians In some way or other the public should be able to discriminate between the skilled optician and the less qualified or unqualified optician or unqualified maker of spectacles At present there were different societies who examined their members and from whom they got the right to put certain letters after their names which indicated that they had undergone a proper test according to the requirements of the society That ought to be sufficient in the public interest The need for optical benefit was now very much better realised than it was a generation or two ago At that time spectacles were considered to do harm to the eyes, and on that account even if they were required they were not used Now the pendulum seemed to have swung rather in the opposite direction, and spectacles for which there might be only the flimsiest pretence of necessity were worn by a great number of people In his experience, which was pretty considerable, he had never known a case where spectacles, however unsuitable, did any harm to the eye at all Considerable discomfort might be caused by unsuitable spectacles, but there was no actual danger of serious injury to the eyes

Lieut -Commander BURNEY The hon. Member has so much knowledge of this subject that I would ask him whether it would be true to say that if unsuitable spectacles were given to a person to correct, say, astigmatism, and he wore them for a year they would not increase the defect from which he was suffering?

SIR GEORGE BERRY said that without answering that specific question he did not agree that it would do any harm On the other hand, spectacles if they were suitable were capable of doing a great deal of good. In that way they could cure squint and double vision, they could prevent headaches, and they could to a certain extent arrest actual diseases of the eye That was the justification for the public having the services of opticians But that did not justify the provisions of this Bill which were calculated to mislead the public and give them a mistaken and therefore undesirable sense of security The public could not generally discriminate between ophthalmic benefit and optical benefit Ophthalmic benefit was very much more complicated, even if they accepted the definition of the term optometry which was given in the Bill Real ophthalmic benefit could be got now because under the National Insurance Act some of the friendly societies were referring their members to ophthalmic surgeons whose names had been given in a list from the Ministry of Health A skilled optician was perfectly competent to undertake the correction of optical defects, which was a simple matter, for the reason that it had been investigated by physicists, physiologists, and ophthalmic surgeons and involved a matter of skill which could be acquired in a few weeks or months But the point of real importance was that the eye was not only an optical instrument which, curiously enough, was less perfect in some respects than the instruments which were produced by human ingenuity, though in other respects, of course, it was more perfect—but the eye was also a percipient sense-organ of most complex structure and functions, and it was associated with other organs of the body It was for that reason that the eye was subject to so many defects and diseases The optician might be able to know of the existence of these diseases, and perhaps to discriminate in some cases between defects due to diseases of the eye and optical defects, but he could not do so without being liable to make a good many mistakes unless he had the full training of a medical man It was owing to the complexity of the eye that the medical curriculum of the universities and the different licensing bodies required the student to take up the study of diseases of the eye in the last six months of his course Before doing so he had to study physics, physiology, pathology, and medicine, and it was only after the completion of those studies that he was able to understand all the functions or organic diseases of the brain, the spinal cord, and the sympathetic nervous system Even then the doctor who wished to specialise in ophthalmic surgery had to undergo a very considerable training both in theory and in practice Without failing in appreciation of the well-qualified optician's work he felt for the reasons he had advanced that it would be wrong to proceed with this Bill

Defective Vision and Public Health

After further discussion,

SIR KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) said that they were unanimous that the subject matter of this Bill touched very closely indeed the question of public health They got a very fair indication of the extent of defective vision from figures which the Board of Education from time to time provided In 1913 it was estimated that not less than 10 per cent of the children of school age suffered from defective eyesight, while in many areas the percentage was as high as 25 per cent In 1920 the average proportion requiring treatment and observation among school-children was estimated at from 10 to 15 per cent, but in 1923 the figure was again found to be about 10 per cent of children at the school-leaving age In 1923 some 135,000 children were ordered spectacles The proportion of children with defective vision to the total number of children inspected in 1924 was 11 1 per cent and in 1925 the figure dropped to 10 2 Therefore the conclusion at which they might very fairly arrive was that the prevalence of defective sight among school-children was fairly constant and was about 10 per cent Last year there was a slight improvement, but he did not know whether they could attach any importance to the figures If they applied these figures to the population generally, and made certain allowances for age and occupation, they could roughly estimate the number of persons with defective sight in England and Wales as about 1 in 5 If that was so there were probably about 8,000,000 people in the country who were affected The general conclusion he should come to from the discussion that had taken place was that undoubtedly there was a case for something to be done, but there was considerable divergence of opinion as to the manner in which the problem should be approached, particularly from the point of view which had been advanced by the medical profession It was true that the doctors had urged with a certain amount of weight that there was an appreciable percentage of cases in which great harm might be done by an optician How far that argument was valid could only be ascertained by a full investigation of the facts The question which they had to face that day was whether in so difficult and complex a matter it was safe to give a second reading to this Bill, or whether it would not be better to leave it to the judgment and recommendation of the Departmental Committee He appealed to the promoters of the Bill under the circumstances to be content with having presented their case to the House and the country and leave it to the Departmental Committee which was a very excellent one The Chairman of the Committee told him that they were already making progress and were ready to come to an impartial judgment on the whole situation

MR RUSSELL said in view of the statement made by the Parliamentary Secretary to the Ministry of Health, which would be appreciated by the promoters of the Bill, he asked leave to withdraw the measure

DR DAVIES withdrew his amendment

Objection was taken to the Bill being withdrawn, and after some further discussion the motion for the second reading was put and negatived without a division.

HOUSE OF LORDS

THURSDAY, MAY 12TH.

SCIENTIFIC RESEARCH.

Lord STANLEY OF ALDERLEY called attention to the Report of the Industrial and Scientific Research Committee. Among the subjects which the Report dealt with, he said, were such things as the preservation of food It was highly desirable that they should not put such things into watertight compartments confining it to the investigation of the problem as it arose in this country He thought that the Committee had recognised the desirability of the question of the preservation and the maintenance of the quality of imported foodstuffs and other articles from the Dominions being investigated even more thoroughly than the easier problem of maintaining the purity and freshness of the foodstuffs produced in this country He would like to learn from the Lord President of the Council (the Earl of Balfour) something of the operations of the Committee of Civil Research, which had been set up by the Government last year It was made clear in the debate last year that the Committee of Civil Research was a link between the Dominions and the Mother Country.

The EARL OF BALFOUR (Lord President of the Council) said that their lordships had reason to be grateful to the noble lord for having called the attention of the House to one of the most important movements of the present day It was a movement which had grown steadily for many years The Committee of Civil Research was already doing an immense amount of very valuable and useful work One of the subjects which had quite recently been under consideration was the tsetse-fly which was one of the most embarrassing scourges of Africa It not only embarrassed agriculture and destroyed animal life, but it also destroyed human life It affected many of our Dependencies, it blasted with its unhappy curse many areas, and it did not fall naturally under the purview of any department For that reason it was exactly one of the subjects with which it was most desirable to deal through the Civil Research Committee Another subject under investigation was that of the native diet in Africa, and another was the Empire supply of quinine Hitherto quinine had been almost entirely derived, he believed, from certain of the Dutch colonies There was no reason that they knew of why that absolutely essential drug should not be cultivated elsewhere and that was being made the subject of inquiry by the Civil Research Committee The British Pharmacopœia, of which a new edition was urgently required, and which ought to be framed; and was being framed, as far as possible on lines suitable to the Empire, was also a subject which had come before the Committee That Committee had no executive powers and no power to spend money Any expenditure which their advice suggested was made on the responsibility of the Government as a whole and with the consent of the Treasury and the Chancellor of the Exchequer The House must not for a moment suppose that the activities of this country in the way of scientific research were exhausted either by the Committee of Industrial Research or by the Committee of Civil Research There was, for example, within the ambit of the Privy Council, the whole immense sphere of medical research Of that he would say nothing that day, but that alone, if the House wished to hear anything about it, would require a debate to itself The work of the Committee of Civil Research and of the Department of Scientific and Industrial Research was but a portion of the Government activities devoted to the great object of applying scientific discovery to the amelioration of the lot of mankind, and perhaps, he ought to add, to the power of one set of men to destroy another which, unfortunately, was also a subject of Government research in all countries of the world at this moment In addition to the eight departments which were already in existence for the purpose of carrying out research, there would have to be, unless he was greatly mistaken, another body created to deal with river pollution That was a subject which was rapidly beginning to cause considerable anxiety to the community from many points of view It was a problem of great difficulty and importance and he believed that it would never be adequately solved without scientific investigation When all had been done that could be done by legislation, and by rearranging, revivifying, or stimulating local authorities, unless they accompanied that improvement of machinery and organisation with an increased knowledge of how they were going to deal with the effluence of factories—of the new sugar factories, for instance—and of sewage, without destroying those industries, they would not satisfactorily solve the problem They had to find some means of safeguarding the needs of their industries while at the same time purifying the water from the point of view of the water-drinker and the fisherman. That was a big problem with which science must deal. The noble earl, in conclusion, asked their lordships to realise the enormous value of the practically unpaid work given by these great men of science to the solution of the problems which were put before them

Lord STANLEY OF ALDERLEY thanked Lord Balfour for the very full reply which he had given to his speech, and still more for the great encouragement which the noble earl's speech would give to scientists

HOUSE OF COMMONS.

WEDNESDAY, MAY 11TH

Playing Fields and Public Health.

Mr JOHN PALIN asked the Minister of Health whether his attention had been called to the shortage of playing fields in many of the cities and towns of the country, and whether, in the interests of public health, he would consider legislation to impose on local authorities the duty of making good this shortage —Mr CHAMBERLAIN replied I am aware that more playing fields are required, although a good deal has been done by local authorities in recent years They were given additional powers by the Public Health Act of 1925 and further legislation is not proposed

Small-pox and Vaccination.

Mr THURTLE asked the Minister of Health in how many of the cases of small-pox which have ended fatally this year vaccination had taken place —Sir KINGSLEY WOOD replied Since the reply given on this subject to the hon and gallant Member for Chelmsford (Lieut -Colonel Howard-Bury) on the 9th inst , a further death has occurred among patients suffering from small-pox Of the 28 cases which have ended fatally this year, 21 were unvaccinated at the time when they acquired infection, while seven had been vaccinated in infancy The ages of the latter at the time when they were attacked by small-pox were 22, 23, 44, 50, 54, 58, and 62 respectively

Mr HARRIS Is the right hon gentleman quite satisfied that the diagnosis proved conclusively that all these cases were small-pox ?

Sir KINGSLEY WOOD I have no reason to doubt the information I have received

Mr DAY Can the hon gentleman say whether any of these cases of small-pox were contracted abroad ?

Sir KINGSLEY WOOD That is another matter. The hon Member had better put down a question

Dr WATTS . Is the hon gentleman aware that the types of cases in the last few months have been more virulent than any we have had for some time ?

Sir KINGSLEY WOOD Yes, I have seen a statement to that effect

Rheumatism in the Navy

Sir BERTRAM FALLE asked the First Lord of the Admiralty the number of boys, second and first class, Royal Navy, at the training establishment, Shotley, who were admitted to sick-quarters and hospital suffering from rheumatism and kindred complaints during the years 1924, 1925, and 1926 , and the number of boys and men under 21 years of age who had been invalided from the Royal Navy owing to rheumatism during the years 1925 and 1926 —Mr BRIDGEMAN replied The following numbers of boys, second and first class, Royal Navy, at the training establishment, Shotley, were admitted to sick-quarters and hospital for "rheumatism" and kindred complaints In 1924, 20 , in 1925, 11 , in 1926, 13 The information asked for in the second part of the question is not readily available and its compilation would involve an expenditure of time and labour which I think my hon friend would not consider justified in the circumstances

Sir BERTRAM FALLE Does my right hon friend not think that some investigation should be made of these cases of rheumatism among first class boys ?

Mr BRIDGEMAN They are kept under observation and the figures do not go to show that there is any increase

Mr T WILLIAMS Would it not be easy to ascertain how many men under 21 have been invalided as a result of contracting rheumatism ?

Mr BRIDGEMAN I hope that the House will not insist on my giving these very detailed figures which may cause an increase in the estimates of my department

Mr T WILLIAMS Is not this a matter of such importance to the health of the men in the Royal Navy that we ought to have these facts and figures before us ?

Mr BRIDGEMAN But we have a medical department who are very diligent in this matter and there is no prima facie evidence that there is anything wrong

Mr T WILLIAMS Are we to understand that the medical officers are satisfied that there are no extraordinary circumstances causing this unfortunate disability ?

Mr BRIDGEMAN I certainly imagine that that is so I shall be only too glad to investigate these cases

Dr VERNON DAVIES Will the First Lord say how many of these cases were invalided out with heart disease ?

Mr BRIDGEMAN I require notice of that question

THURSDAY, MAY 12TH.

Difficulty in Summoning Public Health Nurses

Mr DAY asked the Minister of Health whether his attention had been called to the difficulty in summoning a public health nurse quickly in cases of emergency, as the majority of nurses were not subscribers to the telephone system , and would he consider installing telephones in the residences of all nurses engaged on this work —Mr CHAMBERLAIN replied The answer to the first part of the question is in the negative As regards the second part, this is a matter for the consideration of the bodies by whom the nurses are employed

Small-pox in England and Wales

Mr HARRISON asked the Minister of Health the total number of cases of small pox notified in England and Wales during the last 12 months, and the number of cases that proved fatal —Mr CHAMBERLAIN replied The number of cases of small-pox notified in England and Wales during the 52 weeks ended April 2nd, 1927, was 12,922 The number of deaths registered during the year ended March 31st, 1927, in respect of which small pox was stated on the medical certificate as the cause, or one of the causes, of death was 33 Of this number 32 were classified to small-pox and one to cancer

Mr HARRISON Will the right hon gentleman consider the desirability of making regulations to enable the port sanitary authorities to inquire of persons whether they have come from small-pox infected areas and if so, their destination in this country for the next fortnight after arrival ?

Mr CHAMBERLAIN The officers of my department are taking all steps which are practicable in the circumstances

Mr HARRIS Are the officers of the department perfectly satisfied that all these cases are correctly diagnosed as small pox ? Are not some of the cases supposed to be chicken-pox or some other disease ?

Mr CHAMBERLAIN There are people who would believe that a case of small-pox is anything but small-pox, but they do not include the officers of my department

Lieut -Colonel HOWARD-BURY Is not vaccination the only preventive ?

No answer was given

Mr GROVES asked the Minister of Health whether, in view of the fact that the small-pox cases removed to hospital from Hendon and Golders Green were originally reported as being very mild, he could throw any light on the fatal result in half of them —Mr CHAMBERLAIN replied I do not know to what reports the hon Member refers I am informed that the first of these cases was relatively mild, but that most of the others were severe

Birth Control

Mr THURTLE asked the Minister of Health if, in view of the resolution he had received from a recent national women's conference of one of the political parties represented in this House, in favour of birth control information being given in suitable cases at maternity centres, he proposed to reconsider his attitude on this matter —Mr CHAMBERLAIN replied I do not find that I have received any such resolution as that to which the hon Member refers, but in any case the passing of such a resolution at a party conference would not affect my decision, the reconsideration of which, as previously stated, depends upon an expression of opinion by Parliament

MONDAY, MAY 16TH

Indian Prisoners and Tuberculosis

Mr THOMAS WILLIAMS asked the Under Secretary of State for India whether he would give the names of the prisoners detained under the Criminal Law Amendment Act of 1925 who had, or were, suspected to be suffering from tuberculosis , and whether the Government had under consideration removing these prisoners to surroundings more conducive to the restoration of their health —Earl WINTERTON replied The two persons in question are Jiban Lal Chatterjee and Subhas Chandra Bose The former was removed to a sanatorium a month ago I hope to be in a position to make an announcement about Mr Bose in the course of the next two days

New Site for London University

Mr TREVELYAN asked the President of the Board of Education whether the University of London had arranged to purchase the Bloomsbury site from the Duke of Bedford , what the terms of purchase were , and how much was being provided by His Majesty's Government and how much from other sources —Mr R MCNEILL (Financial Secretary to the Treasury) replied The answer to the first part of the question is in the affirmative, but I am informed that no contract has yet been signed As the Chancellor of the Exchequer stated in November last, he promised in June, 1926, on behalf of His Majesty's Government, that they competent to undertake the correction of optical defects, which was a simple matter, for the reason that it had been investigated by physicists, physiologists, and ophthalmic surgeons and involved a matter of skill which could be acquired in a few weeks or months But the point of real importance was that the eye was not only an optical instrument which, curiously enough, was less perfect in some respects than the instruments which were produced by human ingenuity, though in other respects, of course, it was more perfect—but the eye was also a percipient sense-organ of most complex structure and functions, and it was associated with other organs of the body It was for that reason that the eye was subject to so many defects and diseases The optician might be able to know of the existence of these diseases, and perhaps to discriminate in some cases between defects due to diseases of the eye and optical defects, but he could not do so without being liable to make a good many mistakes unless he had the full training of a medical man It was owing to the complexity of the eye that the medical curriculum of the universities and the different licensing bodies required the student to take up the study of diseases of the eye in the last six months of his course Before doing so he had to study physics, physiology, pathology, and medicine, and it was only after the completion of those studies that he was able to understand all the functions or organic diseases of the brain, the spinal cord, and the sympathetic nervous system Even then the doctor who wished to specialise in ophthalmic surgery had to undergo a very considerable training both in theory and in practice Without failing in appreciation of the well-qualified optician's work he felt for the reasons he had advanced that it would be wrong to proceed with this Bill

Defective Vision and Public Health

After further discussion,

Sir **Kingsley Wood** (Parliamentary Secretary to the Ministry of Health) said that they were unanimous that the subject matter of this Bill touched very closely indeed the question of public health They got a very fair indication of the extent of defective vision from figures which the Board of Education from time to time provided In 1913 it was estimated that not less than 10 per cent of the children of school age suffered from defective eyesight, while in many areas the percentage was as high as 25 per cent In 1920 the average proportion requiring treatment and observation among school-children was estimated at from 10 to 15 per cent, but in 1923 the figure was again found to be about 10 per cent of children at the school-leaving age In 1923 some 135,000 children were ordered spectacles The proportion of children with defective vision to the total number of children inspected in 1924 was 11 1 per cent and in 1925 the figure dropped to 10 2 Therefore the conclusion at which they might very fairly arrive was that the prevalence of defective sight among school-children was fairly constant and was about 10 per cent Last year there was a slight improvement, but he did not know whether they could attach any importance to the figures If they applied these figures to the population generally, and made certain allowances for age and occupation, they could roughly estimate the number of persons with defective sight in England and Wales as about 1 in 5 If that was so there were probably about 8,000,000 people in the country who were affected The general conclusion he should come to from the discussion that had taken place was that undoubtedly there was a case for something to be done, but there was considerable divergence of opinion as to the manner in which the problem should be approached, particularly from the point of view which had been advanced by the medical profession It was true that the doctors had urged with a certain amount of weight that there was an appreciable percentage of cases in which great harm might be done by an optician How far that argument was valid could only be ascertained by a full investigation of the facts The question which they had to face that day was whether in so difficult and complex a matter it was safe to give a second reading to this Bill, or whether it would not be better to leave it to the judgment and recommendation of the Departmental Committee He appealed to the promoters of the Bill under the circumstances to be content with having presented their case to the House and the country and leave it to the Departmental Committee which was a very excellent one The Chairman of the Committee told him that they were already making progress and were ready to come to an impartial judgment on the whole situation

Mr **Russell** said in view of the statement made by the Parliamentary Secretary to the Ministry of Health, which would be appreciated by the promoters of the Bill, he asked leave to withdraw the measure

Dr **Davies** withdrew his amendment

Objection was taken to the Bill being withdrawn, and after some further discussion the motion for the second reading was put and negatived without a division

HOUSE OF LORDS

Thursday, May 12th

Lord **Stanley of Alderley** called attention to the Report of the Industrial and Scientific Research Committee. Among the subjects which the Report dealt with, he said, were such things as the preservation of food It was highly desirable that they should not put such things into watertight compartments confining it to the investigation of the problem as it arose in this country He thought that the Committee had recognised the desirability of the question of the preservation and the maintenance of the quality of imported foodstuffs and other articles from the Dominions being investigated even more thoroughly than the easier problem of maintaining the purity and freshness of the foodstuffs produced in this country He would like to learn from the Lord President of the Council (the Earl of Balfour) something of the operations of the Committee of Civil Research, which had been set up by the Government last year It was made clear in the debate last year that the Committee of Civil Research was a link between the Dominions and the Mother Country

The **Earl of Balfour** (Lord President of the Council) said that their lordships had reason to be grateful to the noble lord for having called the attention of the House to one of the most important movements of the present day It was a movement which had grown steadily for many years The Committee of Civil Research was already doing an immense amount of very valuable and useful work One of the subjects which had quite recently been under consideration was the tsetse-fly which was one of the most embarrassing scourges of Africa. It not only embarrassed agriculture and destroyed animal life, but it also destroyed human life It affected many of our Dependencies, it blasted with its unhappy curse many areas, and it did not fall naturally under the purview of any department For that reason it was exactly one of the subjects with which it was most desirable to deal through the Civil Research Committee Another subject under investigation was that of the native diet in Africa, and another was the Empire supply of quinine Hitherto quinine had been almost entirely derived, he believed, from certain of the Dutch colonies There was no reason that they knew of why that absolutely essential drug should not be cultivated elsewhere and that was being made the subject of inquiry by the Civil Research Committee The British Pharmacopœia, of which a new edition was urgently required, and which ought to be framed; and was being framed, as far as possible on lines suitable to the Empire, was also a subject which had come before the Committee That Committee had no executive powers and no power to spend money Any expenditure which their advice suggested was made on the responsibility of the Government as a whole and with the consent of the Treasury and the Chancellor of the Exchequer The House must not for a moment suppose that the activities of this country in the way of scientific research were exhausted either by the Committee of Industrial Research or by the Committee of Civil Research There was, for example, within the ambit of the Privy Council, the whole immense sphere of medical research Of that he would say nothing that day, but that alone, if the House wished to hear anything about it, would require a debate to itself The work of the Committee of Civil Research and of the Department of Scientific and Industrial Research was but a portion of the Government activities devoted to the great object of applying scientific discovery to the amelioration of the lot of mankind, and perhaps, he ought to add, to the power of one set of men to destroy another which, unfortunately, was also a subject of Government research in all countries of the world at this moment In addition to the eight departments which were already in existence for the purpose of carrying out research, there would have to be, unless he was greatly mistaken, another body created to deal with river pollution That was a subject which was rapidly beginning to cause considerable anxiety to the community from many points of view It was a problem of great difficulty and *importance* and he believed that it would never be adequately solved without scientific investigation When all had been done that could be done by legislation, and by rearranging, revivifying, or stimulating local authorities, unless they accompanied that improvement of machinery and organisation with an increased knowledge of how they were going to deal with the effluence of factories—of the new sugar factories, for instance—and of sewage, without destroying those industries, they would not satisfactorily solve the problem They had to find some means of safeguarding the needs of their industries while at the same time purifying the water from the point of view of the water-drinker and the fisherman That was a big problem with which science must deal The noble earl, in conclusion, asked their lordships to realise the

MANIA AND DEPRESSION.

To the Editor of THE LANCET.

SIR,—Dr Snowden's paper entitled the Psychological Treatment of Mania and Depression in your current issue will be read with great interest, but on perusing the cases he quotes it seems to me that the title he uses is a misnomer Of the three cases described surely the first two would ordinarily be classed as examples of anxiety hysteria On the one hand, both present common symptoms of that disorder, and on the other, several facts which have been brought out by Dr. Snowden seem to differentiate them from mania, as that term is understood in psychiatry For example, of the first patient Dr Snowden says that his restless condition made him acutely miserable and fearful of insanity Neither of these symptoms is in any way characteristic of mania, in fact, taken together they would usually be considered to rule that diagnosis out of court The second patient's fear of suicide, to name only one symptom, is similarly highly incongruous with the classical manic syndrome If the third case be taken as an example of psychotic depression, as Dr Snowden obviously wishes us to do, is it not true that this condition usually terminates spontaneously in recovery, and is there then any criterion by which we can judge of the effect of treatment in a single case?

With regard to a medico-legal point; if certifiable patients need not be certified, but are to be sent to nursing homes, it seems only fair that we should carefully warn the matrons of these homes that, if they receive our patients, they are liable to prosecution, and *that possibly they may* be mulcted in heavy fines.

I am, Sir, yours faithfully.

T A ROSS

The Cassel Hospital for Functional Nervous Disorders,
Penshurst, Kent, May 14th, 1927

THE SURGERY OF HERNIA.

To the Editor of THE LANCET

SIR,—In reading the very interesting Hunterian lecture on Recent Advances in the Surgery of Hernia, by Mr. Ernest M. Cowell (THE LANCET, March 5th, p 479), I remembered seeing the late Prof O. Witzel, of Düsseldorf, do filigree operations for the closure of large herniæ when I visited his clinic (at that time at Bonn) in 1899 His teacher, Prof. Trendelenburg, had *some years earlier* (1890) closed the large aperture of a scrotal hernia by the insertion of a disc of fresh bone and later on *had repeated these* operations, using flaps of bone covered with periosteum His assistant, Goepel, began in 1897 to use silver filigree instead of bone plates, *but* he only published his results in the *Centralblatt für Chirurgie*, No 17, of 1900, after Witzel had described his method in No 10 of the same year. I was so struck by the utility of the method that I at once adopted it and did quite a number of these operations at the German Hospital in London, at first making my own filigrees and later on using ready-made filigrees sold by Otto Möcke of Leipzig In later years I have used more frequently free fascial grafts but even now sometimes find the filigrees very useful

I think Mr Cowell cannot be right in saying that Celsus practised herniotomy, as he was not himself a medical man *but* a lay writer who collected and published the medical knowledge of his time

I am, Sir, yours faithfully,

J P. ZUM BUSCH.

Kantonsspital Liestal (Switzerland), May 10th, 1927

THE MASTOID ANTRUM IN THE CHILD.

To the Editor of THE LANCET

SIR,—In their account last week (p 1024) of a case of facial paralysis of aural origin in a 7 weeks' infant, Dr Hobhouse and Mr Marshall write. "Considering the negligible size of the mastoid antrum at this age, the locality in which so large a quantity of pus was contained is rather difficult to determine." The mastoid or tympanic antrum at this age is not negligible *in size* On the *contrary*, it *is fully* developed at birth and is not only relatively, but actually, as large as the adult antrum The tympanic antrum of a 7 weeks' old infant will hold pus "in sufficient quantity to fill the external meatus" several times over —I am, Sir yours faithfully,

F PEARCE STURM, M Ch,

Aurist and Laryngologist, Leigh Infirmary, Lancashire
May 16th, 1927

THE RÖSE-GOTTLIEB METHOD OF MILK ANALYSIS

To the Editor of THE LANCET

SIR —In an article on dried milk in your issue of April 23rd (p 878) it is implied that the Röse-Gottlieb method for fat estimation gives results which are too low when used with dried milk, and could only be expected to give satisfactory results with liquid milk May I point out that if the essential conditions of the Röse-Gottlieb method are complied with—i e that the dried milk must be completely dissolved, and the reagents added in their proper order—the method is most reliable and exact for all milk products including dried milks I published a paper on the essential details in the *Analyst*, 1908 (p. 389) and have since repeated them in "Dairy Chemistry," second and third editions, and in the "Laboratory Book of Dairy Analysis," *second and third* editions.

I am, Sir, yours faithfully,

Nottingham, May 13th H DROOP RICHMOND, F I C.

THE PREVENTION OF SCARLATINAL NEPHRITIS A CORRECTION.

To the Editor of THE LANCET.

SIR,—In your report (THE LANCET, May 7th, p 971) of a contribution read by Dr. H Carter and myself before the Medical Section of the Royal Society of Medicine on April 26th on this subject, there is an error in the dosage stated—"0 90 g" should read "90 gr" a day This dose certainly represents the *minimum* amount of alkali *per diem* which has proved to be to some extent effective in preventing the development of albuminuria and nephritis in scarlet *fever* The incidence of these complications was reduced from 5 5 per cent in the control cases to 0 6 per cent on this *dose A larger* dose might possibly afford absolute protection but this point is still being investigated Until *further* evidence is obtained it is therefore impossible to state whether or not alkalis will prove to be completely protective and, if so, in what doses

I am, Sir, yours faithfully,

London, May 9th, 1927 A ARNOLD OSMAN.

THE ORIGIN OF LEUKÆMIA

To the Editor of THE LANCET.

SIR,—In an attempt to investigate the origin of leukæmia (lymphatic and myeloid) I have come across some evidence to connect it with (*a*) shock or nervous exhaustion, and (*b*) malaria *This may*, however, be a coincidence, and as the references in the literature of the subject are very scanty, I should be grateful to any of your readers if they could let me have notes of any cases in which either of these factors appeared to be concerned with the subsequent onset of leukæmia The length of the interval is important.

I am, Sir, yours faithfully,

Bedford-sq, W C, May 16th A. KNYVETT GORDON would be prepared within certain financial limits to ask Parliament to make provision for improved accommodation of the University, subject to approval by the Treasury of plans to be formulated by the Senate No official intimation has yet reached the Treasury, and I am at present unable to give any further information save that the amount which Parliament would be asked to provide towards the improved accommodation of the University would be approximately one-half the price paid by the Government for the Bloomsbury site, which was £425,000

Poor-law Relief

Mr NEIL MACLEAN asked the Minister of Health the number of people in receipt of Poor-law relief in England and Wales in 1925 and 1926 —Mr CHAMBERLAIN replied The total number of persons in England and Wales in receipt of Poor-law relief, including lunatics in asylums, casuals, and persons receiving domiciliary medical relief only, on the night of Jan 1st, in the years 1925 and 1926, was 1,205,267 and 1,439,810 respectively

Canned Goods and Preservatives

Mr HURD asked the Minister of Health what classes and quantities of canned goods were imported into this country which, because of the presence in them of preservatives, artificial colouring matter, or for other similar reasons, were barred by law for use in the countries of origin —Sir KINGSLEY WOOD replied The Preservative Regulations, which prohibit or restrict the addition of preservatives or colouring matters to foodstuffs, are so drawn as to prevent the importation of articles which do not conform to their requirements, and my right hon friend is not aware that any canned goods are imported into this country the sale of which is prohibited in the countries of origin for the reason stated in the question

TUESDAY, MAY 17TH

Small-pox in Durham

Mr BATEY asked the Minister of Health the number of persons who contracted small-pox in the county of Durham for the years 1924, 1925, and 1926 —Sir KINGSLEY WOOD replied The figures are as follows 1924, 20 cases , 1925, 1138 cases , 1926, 6645 cases

The Use of Tins as Milk Containers

Mr MACQUISTEN asked the Secretary of State for Scotland whether, as small farmers and other milk producers who sold their milk out of barrels were now being ordained to use tins, which were less sanitary in summer, and the use of which caused the loss and compelled them to incur the cost of reconstructing their carts, he would suspend the order compelling them to use tins until their existing equipment had to be replaced —Sir JOHN GILMOUR replied I am advised that wooden vessels are not more sanitary in summer than the metal vessels used for milk, and that the practice of using wooden vessels for the sale of milk is not common in Scotland The Milk and Dairies (Scotland) Order, 1925, which prohibits, from Jan 1st last, the use of wooden vessels for milk except in the case of buttermilk, was issued nearly two years ago, and so substantial notice has been given I see no reason to take any action to suspend or revoke the order on this point

Registration of Illegitimate Births

Mr HORE-BELISHA asked the Minister of Health whether he had now made inquiries into the administration of the Legitimacy Act, 1925 , and whether he had found it possible to ameliorate the present conditions and arrange that a certificate on re-registration should not be distinguishable from any ordinary birth certificate —Sir KINGSLEY WOOD replied My right hon friend has considered this matter carefully The arrangements for the re-registration of births under the Legitimacy Act, 1926, have been so framed as to render the entry indistinguishable from that of an ordinary legitimate birth wherever this has been possible without hardship to the parties, and it would not be possible to take any further measures without amending the whole of the general registration law I may add with reference to the particular points which the hon Member has in mind, that all entries of births registered after the expiration of 12 months are required to contain the words, " on the authority of the Registrar-General," and must bear the date on which they are registered

WELLCOME HISTORICAL MEDICAL MUSEUM —At 8 30 P M. on May 24th Mr Henry Wellcome will hold a conversazione at this museum for the Royal Anthropological Institute of Great Britain and Ireland Prof Elliot Smith, F R S , will give an address on the medical and magic nature of the anthropological collections in the museum

The death, from pleuro-pneumonia, is reported of Surg Lt -Comdr George Aubrey, R N , at Hong-Kong Appointed lieutenant in 1917, he saw active service during the war, and after being employed at Dunkirk in 1919 he went to Malta and was specialist in bacteriology and pathology at the hospital there In 1922 he joined the *Ajax* in the Mediterranean, in 1923 he was with the submarine *Adamant*, and in 1925 was attached to the surveying ship *Kellett* Promoted to Surg Lt -Comdr in 1923, he had passed for Surg -Comdr

AMBULANCE CHALLENGE SHIELD COMPETITION

The annual competition for the Territorial Army Ambulance Challenge Shield will be held at the Royal Army Medical Corps Headquarters, Upper Chorlton-road, Manchester, on Saturday, May 21st Teams from the following Territorial Army Field Ambulance units will compete for the trophy 125th (E Lancs), 128th (Wessex), 140th (County of London), 143rd (S Midland), who are the holders, 158th (Welsh), 164th (W Lancs), 167th (City of London), and 170th Cavalry

A MANCHESTER NURSES' HOME —On Saturday last Princess Mary laid the foundation-stone of the new nurses' home of the Manchester Royal Infirmary, and afterwards visited Booth Hall Infirmary, where she unveiled name-plates on the pavilions

EVELINA HOSPITAL FOR SICK CHILDREN.—There were 61,000 attendances of out-patients at this Southwark hospital last year; the in-patients numbered 700.

ROYAL INSTITUTE OF PUBLIC HEALTH.—The general and sectional programmes of the Institute's congress at Ghent, Belgium, from June 1st to 6th, have now been issued, and may be obtained from the hon. secretaries at 37, Russell-square, London, W.C. 1.

UNIVERSITY OF MANCHESTER.—About £5000 has been received from an anonymous donor to endow two post-graduate scholarships for research in biology.—The Dauntesey Medical Senior Scholarship has been awarded to W. W. Kay.

MILFORD SANATORIUM.—Lord Ashcombe, Lord-Lieutenant of Surrey, last week laid the foundation-stone of the central block of the Surrey County Sanatorium at Milford, near Godalming. The institution will accommodate 500 patients, and the cost, exclusive of the site, will be nearly £200,000.

LAMBETH GENERAL LYING-IN HOSPITAL.—Last year there were 991 in-patients, who contributed £1357 from their "maternity benefits." Under the terms of its lease the hospital is bound to build a new nurses' home which will cost £40,000; plans have been prepared for its erection, but the money has yet to be raised.

INSTITUTE OF HOSPITAL ALMONERS.—A meeting will be held at the Grotrian Hall, Wigmore-street, London, on Thursday, May 26th, at 5 P.M., when Sir John Rose Bradford, Sir Berkeley Moynihan, Sir Arthur Stanley, and Dr. A. C. E. Gray will speak on Hospital Social Service. A limited number of invitation cards may be had from the secretary of the Institute at 296, Vauxhall Bridge-road, S.W. 1.

DEATH UNDER ANÆSTHESIA.—The accidental use of a mixture of carbon dioxide and oxygen, in the proportion of 80 parts carbon dioxide to 20 parts oxygen, was responsible for a death under anæsthesia at St. Bartholomew's Hospital on May 11th. The mistake occurred when the anæsthetist, proposing to induce with gas and oxygen, turned on a cylinder containing carbon dioxide instead of the one containing nitrous oxide. At the inquest held on May 14th by Mr. Danford Thomas it was stated that the carbon dioxide cylinders are painted green down the sides, but black on the top, and the anæsthetist had been standing over the cylinders when he turned them on, and from this position failed to observe the distinguishing mark. The autopsy was performed by Sir Bernard Spilsbury, who said that the cause of death was asphyxia from carbon dioxide gas. All efforts to restore animation failed, including heart massage and artificial respiration. The verdict recorded was death from misadventure.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—Mr. J. Swift Joly will give a special clinical demonstration at St. Peter's Hospital on Wednesday, May 25th, at 2 P.M. On the same day, at 1 P.M., Mr. H. Neame will demonstrate at the Royal London Ophthalmic Hospital. On Thursday, May 26th, at 2.15 P.M., Dr. E. G. B. Calvert will give a clinical demonstration at the Royal Northern Hospital. All these demonstrations are open to medical practitioners without fee. From June 8th to 21st the Chelsea Hospital for Women will hold a special course in gynæcology (fee £5 5s.). A four weeks' afternoon course will be held at the Central London Ophthalmic Hospital from June 8th to July 2nd. Instruction will be given in the out-patient department, and there will be lectures on the more important diseases of the eye. An operative course will be arranged if desired. (Fee, £3 3s. for the clinical course and £5 5s. for the operative class.) From June 13th to 25th a course in diseases of children will be given at the Children's Clinic. Sessions will also be held at the Hospital for Diseases of the Heart, Bethlem Royal Hospital, Royal National Orthopædic Hospital, the Royal Waterloo Hospital, and elsewhere. (Fee £2 2s.) An afternoon course has been arranged at the Hospital for Diseases of the Skin, Blackfriars, from June 20th to July 1st. On each Tuesday cases of special interest will be shown. (Fee £1 1s.) From June 27th to July 9th the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E., will provide a special course. The entire practice of the hospital will be open to those enrolling. The Fellowship can arrange for practical courses in anæsthetics and obstetrics, and can also make arrangements for clinical assistantships in gynæcology. A general course of instruction is also provided at the associated hospitals, for which a separate programme is published. Copies of all syllabuses and of the *Post-Graduate Medical Journal* may be obtained from the Secretary of the Fellowship at 1, Wimpole Street, W.1.

Obituary.

NEVILLE THOROLD WOOD, M.D. DURH., M.R.C.P. LOND.

Dr. Neville Wood, who died on May 14th at the age of 69, was well known in London for his exceptional knowledge of British and foreign spas and of the conditions to which their methods of treatment are suited. He was educated at Eastbourne College and St. George's Hospital, and after qualifying as M.R.C.S. Eng. in 1883 continued his medical study at Paris and perfected a knowledge of French which afterwards served him well. He became a Member of the Royal College of Physicians of London in 1892 and graduated M.D. Durh. in 1899. The intervening years were occupied in private practice, but he continued to enlarge his hospital experience by a number of appointments which included clinical assistantships at the Chelsea Hospital for Women, the Victoria Hospital for Children, and the London Throat Hospital. Later he held a similar appointment at the Royal Westminster Ophthalmic Hospital, and at the time of his death he was consulting physician to the Kensington Children's Hospital and Dispensary. His special interests, however, were in medical hydrology, and his writing contributed a good deal towards the more intelligent use of climatic and other natural resources. He was one of the early members of the British Balneological and Climatological Society, founded in 1895, which was the first attempt to organise the medical profession at the health resorts and to stimulate the development of the science of waters and climates in this country. He subsequently held the office of President when this Society became a section of the Royal Society of Medicine, and on behalf of a committee of that section edited a volume entitled "Health Resorts of the British Islands" (1912) which was well received and was translated into French. Like the "Climates and Baths" of the Royal Medical and Chirurgical Society (1895) it contains articles of permanent value, especially those in which competent authorities have described the climates that distinguish the different sections of the British coasts, and undoubtedly it contributed to the new and comprehensive view of these localities as a medical and national asset.

"Neville Wood," writes a colleague, "was a strenuous worker. Like his own handwriting he was forcible, a little angular, and at times hard to comprehend, but he had generous impulses and a kind heart. When I saw him last after long illness and many operations he was still occupied with objects of interest and expatiating with pleasure upon the beauties of colour."

A man of varied talents, Dr. Wood enjoyed a good general practice in Kensington. He was at one time President of the West London Medico-Chirurgical Society and was a corresponding member of the American Clinical Climatological Society.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 7TH, 1927

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 337 (last week 277); scarlet fever, 1375; diphtheria, 793; enteric fever, 34; pneumonia, 884; puerperal fever, 35; puerperal pyrexia, 101; cerebro-spinal fever, 14; acute poliomyelitis, 6; encephalitis lethargica, 43; typhus fever, 1; dysentery, 5; ophthalmia neonatorum, 124. No case of cholera or plague was notified during the week. The single case of typhus fever was notified in Sunderland Port Sanitary District.

Cases of small-pox were notified from the counties of Derby 16, Durham 164, Middlesex 1 (Hendon), Northumberland 29, Nottingham 3, Stafford 1, Yorks East Riding 1

RADIOGRAPHY IN THE TREATMENT OF FRACTURES

To the Editor of THE LANCET

SIR,—Enclosed I am forwarding you a copy of a letter which the Todmorden Medical Society are submitting to the Medical Defence Union.

I am, Sir, yours faithfully,
C LEONARD WILLIAMS,
Hon Secretary, Todmorden Medical Society
Roomfield, Todmorden, May 16th, 1927

[ENCLOSURE]

DEAR SIR,—The Todmorden Medical Society views with apprehension the attitude of the Medical Defence Union as expressed in and by their recent circular letter adverting to radiography in the treatment of fractures

This circular letter must prejudice the case of any medical man who may be sued by an aggrieved patient, the subject of a fracture, if the practitioner has not obtained a radiogram, notwithstanding any circumstance which may have enabled the practitioner in the exercise of his discretion to dispense with such a radiogram, and notwithstanding any difficulties or dangers which might have been incurred in obtaining any such X ray report

This prejudice you have achieved by your letter throws on any defence the obligations of proving in any case as a matter of necessity that any such omission is justified either by the rightful discretion of the practitioner or by the special circumstances in which he acted, and establishes an atmosphere in which any such practitioner is pre-judged negligent until he has proved to the contrary For this legal disability medical men are indebted to the Medical Defence Union

Your letter, too, by laying down a principle of such a nature must in no small measure enlarge the discretion of your executive in denying liability to support a certain number of defences, and to this extent diminishes the liabilities for which practitioners, not without some reasonable justification, may consider themselves covered by you

Your policy also of creating amongst general practitioners a spirit of dependence in which they rely essentially on the ancillary medical services, re-acts adversely on the best interests of general practice

These ancillary services are invaluable in their place but the policy you have adopted is far wider than the specific recommendations you have made, and if pursued by making medical men into retail purveyors of X ray, biochemical, bacteriological, and other reports, must tend to diminish the interests of the general practitioner adversely, to the interests of the public

Situated as we are in Todmorden radiography is a possibility only where special circumstances indicate the necessity

Our attitude to the question is therefore the antithesis of yours which we claim is bad in principle and inapplicable to the circumstances of the area we serve and of many other localities, too, where the population is scattered and sufficiently far removed from the available special services to make their application always difficult, sometimes a danger.

We beg leave to submit the publication of your circular was an indiscretion, and beg to ask you what you propose doing in the circumstances, particularly with reference to your future policy, please

Yours faithfully,
(Signed) C LEONARD WILLIAMS,
Hon Secretary, Todmorden Medical Society
April 21st, 1927

⁂ The letter of the Todmorden Medical Society, which we are invited to publish, introduces a subject of importance It is a duty of the great majority of the medical profession to join one of the protection and defence associations, and the attitude of the Medical Defence Union has the sympathy of the London and Counties Medical Protection Association The difficulties, however, are recognised of absolute adherence to any rule that photographs must have been taken in certain cases Protection and defence corporations act strictly in the interests of their clients, though all will sympathise with the fine professional attitude taken up by the Todmorden Medical Society Where the practitioner can show that the difficulties in obtaining a safeguard (in the patient's interests as much as in his own) were material, a jury, when a quarrel arose, would certainly take that fact into consideration, but a jury might not regard the facts in the same favourable way if the safeguard had been withheld upon professional grounds It is common prudence for any practitioner, who has a case to deal with when an X ray photograph would throw light upon the circumstances, to suggest to the patient, or to those responsible for the patient, that such a procedure should be followed It need hardly be said that if the patient, directly or indirectly, is responsible for the omission to take the photographs, any charge of neglect brought against the practitioner falls to the ground —ED L

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON —An extraordinary Comitia of the College was held on May 12th, when the following were admitted to the Fellowship —

Drs W S Paget Tomlinson, George Hall, D E Core H P Newsholme, A W Stott, Prof G H Monrad-Krohn Dr T H G Shore Maj V B Green Armytage Surgeon Rear Admiral R St G S Bond Drs M Davidson, T Izod Bennett, E Mapother, C F T East, and Prof H MacLean

Under By law XXXVIII *(b)* Dr Andrew Balfour and Sir Squire Sprigge

The Registrar reported the acceptance of the post of junior standing counsel to the College by Mr C Stafford Crossman, and that of delegate to the third Imperial Social Hygiene Congress by Dr S W Wheaton —A letter from the secretary of the Medical Research Council, regretting the inability to resume publication of *Medical Science Abstracts and Reviews*, was read —Dr L S T Barrett was appointed the delegate of the College to the thirteenth annual conference of the National Association for the Prevention of Tuberculosis

ROYAL COLLEGE OF SURGEONS OF ENGLAND —At a meeting of the Council held on May 12th, Sir Berkeley Moynihan, the President, in the chair, Mr C F Beadles and Sir Henry Gauvain were admitted to the Fellowship The diploma of Fellow was also conferred on Mr G F Gibberd and Mr A J Wrigley Mr E Miles Atkinson received the Jacksonian Prize for 1926 for his essay on the Pathology, Diagnosis, and Treatment of Abscess of the Brain Mr H C Malleson received the John Tomes prize for 1924–26 for his work on the Histology and Pathology of the Dental Tissues Mr R G Wilbond *signed the roll of* Begley students —The President reported that the new by-laws had been approved and signed by the Secretary of State for Home Affairs, the Lord Chancellor, and the Lord Chief Justice —Diplomas of M R C S were conferred upon 163 candidates (135 men and 28 women) whose names were published in THE LANCET, May 7th, p 1005

The *Jacksonian Prize* for 1927, which is of the value of £19 10*s*, will be awarded for a dissertation on the Pathology, Diagnosis, and Treatment of Bronchiectasis and Abscess of the Lung The subject for 1928 will be the Surgical Treatment of Pulmonary Tuberculosis *Candidates must be either* Fellows or Members of the College, and the essays must be submitted by Dec 31st Further particulars may be had from the secretary

UNIVERSITY OF LONDON —Mr Walter George Spencer, consulting surgeon to the Westminster Hospital, has been elected to the Senate as medical representative of Convocation Like all the other successful candidates for election, Mr Spencer was the nominee of the University of London Graduates' Association, of whose council he is a member

University College —An address on Lord Lister and the Romance of Surgery will be given at the College on May 23rd, at 5 30 P M, by Mr Raymond Johnson Dr A M H Gray will preside

St Mary's Hospital Medical School —There will be a distribution of prizes by Field Marshal Lord Allenby on Wednesday, June 8th, at 3 P M

London Hospital Medical College —On Wednesday, June 29th, at 3 P M, Lord Eustace Percy, M P., President of the Board of Education, will distribute prizes in the College Library

MEDICO-LEGAL SOCIETY.—An ordinary meeting of this Society will be held at 11, Chandos street, Cavendish-square, London, W 1, on Thursday, May 26th, at 8 30 P M, when Sir Lenthal Cheatle will read a paper on Some Medico-Legal Aspects in the Fracture of Bone A discussion will follow Members may introduce guests to the meeting on production of a member's private card

Hospitals Congress and Exhibition —The fourth annual congress of the Incorporated Association of Hospital Officers will be held at the Royal Horticultural Hall, Westminster, on Friday and Saturday, May 27th and 28th, under the presidency of Sir Arthur Stanley, when the subjects for discussion will be hospital policy, with particular reference to the raising of funds, and hospital planning and construction During the congress there will be an exhibition to illustrate up-to-date hospital construction equipment and domestic management This exhibition, the first of its kind in this country, will be opened by H R H Princess Arthur of Connaught at noon on Thursday, May 26th

(Hull), North Riding 3 (Middlesbrough), West Riding 51, Brecknock 2 (Brynmawr), Monmouth 66

Deaths —In the aggregate of great towns including London there were 4 (0) deaths from small-pox, 3 (0) from enteric fever, 57 (1) from measles, 4 (1) from scarlet fever, 34 (13) from whooping-cough, 25 (5) from diphtheria, 50 (11) from diarrhœa and enteritis under 2 years and 57 (7) from influenza The figures in parentheses are those for London itself

SMALL-POX IN LONDON —Six out of 11 cases of small-pox reported in the London area have now proved fatal, and the chairman of the Public Health Committee remarked in the London County Council on Tuesday that the disease in London was more severe than that prevalent in the Midlands and Northern area There could be little doubt, he added, that the outbreak was attributable to some undisclosed cause or causes imported from abroad All except two of these cases were notified to the Hendon Urban District Council, although two of them were discovered in a nursing home in Hampstead under treatment for supposed chicken-pox A single case had been reported in each of the metropolitan boroughs of Hampstead and Poplar The London County Council has agreed to distribute precautionary circulars where this seems advisable through its school organisation

Thursday, May 26th —5 P M, Prof Hugh MacLean Insulin in the Treatment of Diabetes and Some Other Nutritional Disturbances

GUY'S HOSPITAL MEDICAL SCHOOL, London Bridge, S E

Friday, May 27th —5 30 P M, Prof E H Kettle Inflammation and Infection (Second of four free lectures) corridor, on the other hand, found in so many American hospitals, is not a feature of the plan which he would like to see followed, and in this respect the European hospitals appear to have the advantage in point of cheerfulness and health In comparing the vertical and horizontal systems of planning, there are points in favour of each, but on the question of extension (which is of primary importance to hospitals), there is little doubt the horizontal system is easier to handle. Mechanical efficiency is found most highly developed in America but reliance in mechanical means has certain drawbacks, and the case of mechanical ventilation may be given as an instance. The saving of labour however, is so important that attempts in that direction ought to be welcomed.

Oil-fuel installations are being adopted increasingly, as they result in the saving of labour caused by the handling of coke and ashes and they also have the advantage of greater cleanliness Finally, the question of architectural interest and beauty is now recognised to be just as important for hospitals as it is for banks, churches and private residences The general level of hospital design is now very high, and the fact that funds are invariably limited has not been altogether a disadvantage for it has often resulted in a dignified simplicity which expresses the character and purpose for which the building has been erected

---

COLONIAL HEALTH REPORTS

BRITISH GUIANA

A REPORT prepared by Mr B H. Bayley, acting Assistant Colonial Secretary, on the affairs of this colony for the year 1925 has been issued The estimated population on Dec. 31st was 304,412 (154,543 males and 149,869 females) 10,197 births (5276 boys and 4921 girls) were registered during the year The birth-rate was 33·5 per 1000 of the population. The deaths were 7352—24·2 per 1000 The birth- and death-rates per 1000 of the estimated population of each of the several races representing the community were as follows —

Races	Birth-rate per 1000.	Death-rate per 1000
Europeans (other than Portuguese)	10·7	8·6
Europeans (Portuguese)	24·1	21·1
East Indians	37·3	27·7
Chinese	30·9	16·7
Aborigines	34·8	20·8
Blacks	29·7	23·1
Mixed races	37·7	18·2

The number of children who died under 1 year of age was 1582, or 155 per 1000 births, for 1925, as compared with 1606, or 165 per 1000 births in 1924 A new hospital built by the Demerara Bauxite Company on the Demerara River where the company's plant is situated, was formally opened in May. It serves a large number of people not only at Mackenzie, but also over a wide area of country, and can accommodate 80 patients. The Bauxite Company carries on a continuous campaign against malaria with satisfactory results and ankylostomiasis has already been eradicated from the company's labouring force.

The climate, although warm is distinctly cooler than that of other British colonies in tropical latitudes and Europeans and other Northern races enjoy consistently good health. The mean temperature throughout the year was 80·3° F. the mean maximum being 90° and the mean minimum 69°. The heat, which is greatly tempered by cooling breezes from the sea is felt most from July to October, owing to decreased force of these breezes There are annually two wet seasons, from April to the middle of August and during December and January The annual rainfall for the past 45 years averaged 91·65 inches in Georgetown. The rainfall in 1925 was 63·25 inches as compared with 83·54 in 1924 Sir Cecil Rodwell K.C M G, who succeeded Sir Graeme Thomson, K C B, as Governor, arrived in British Guiana and assumed the government of the colony on Nov. 20th

FIJI.

Mr. D R. Stewart, the acting Colonial Secretary, has furnished a report for the year 1925, in which he states that the general health was satisfactory, apart from an epidemic of typhoid fever in Suva, in which there were 350 cases and 28 deaths. Whooping-cough and influenza were prevalent throughout the colony, but there was very little dysentery and no other serious infectious disease. Continued progress was made in the campaign against ankylostomiasis. This disease is no longer a prevalent cause of debility of the Indian population. Practically the whole population has received one treatment, and those living in the wet districts, where it was formerly most prevalent, a second treatment. The Makogai Leper Asylum received during the year patients from Samoa, New Zealand, and Niue, and arrangements are complete to receive those from Tonga and the Cook Islands Over 5000 injections of salvarsan were given during the year, and secondary and tertiary yaws are steadily decreasing. The Lautoka hospital with 46 beds for East Indians and nine for Europeans was opened towards the end of the year The vital statistics remain satisfactory, except in so far as the death-rate of the Fijian population is concerned. The deaths during the year and the percentages of the respective classes of population were as follows Europeans 37, being 0·90 per cent.: Fijians 2012, being 2·2 per cent.; Indians 494, being 0·72 per cent , others (excluding Rotumans) 61, being 0·86 per cent. The births were as follows: Europeans 68, being 1·66 per cent.; Fijians 2856, being 3·22 per cent.; Indians 2258, being 3·31 per cent.: others (excluding Rotumans) 169, being 2·46 per cent. 1121 marriages were registered, being at the rate of 0·066 of the population. During the year 2437 persons arrived in the colony and 2457 departed Arrivals and departures were almost all residents in the colony There was no repatriation steamer for Indians during the year, as it was not found possible to arrange a charter The mean maximum temperature for the year was 82·7, and the mean minimum 70·6 The highest recorded was 91 on Feb 6th and the lowest 59·8 on July 3rd. Rain fell on 217 days during the year, with a total fall of 106·66 inches The greatest fall in 24 hours was 5·84 inches on Sept. 11th. The trade winds were exceptionally light and unreliable during the season. There were 21 thunder-storms

The islands of Fiji owe their origin in part to volcanic upheaval. There are, however, now no active volcanoes, but several of the high mountains were formidable craters in past times In several places hot springs are met with, those best known being situated at Savusavu, on the island of Vanualevu, on the Wadina River, north of Suva, and on several of the islands of the Lomaiviti group The highest altitude reached is Mount Victoria (4550 feet) Most of the islands are practically surrounded by coral reefs between which and the shore there is provided a well-protected waterway.

BARBADOS

Mr. J. B Howell, acting Colonial Secretary, is responsible for the report for 1925–26 just issued. It states that the population on Dec. 31st 1925, was estimated to be 162,211, but as this estimate depends on emigration and immigration figures, which experience has often shown to be seriously inaccurate, not much reliance can be placed upon it. The change in the immigration laws of the United States has put a stop to the rush of emigration to America as the annual quota now allowed is about 60, whereas in 1923 over 1700 persons emigrated to the States, and the number was tending to increase, as those who had settled there sent money to their relations and friends to enable them to join them. The birth-rate during the year was 34·85 per 1000, and the death-rate 29·46 The percentage of illegitimate births was 70·92 In January 1925 a Registration of Deaths Act came into force: there was no registration prior to that date. The following is a table of the principal causes of death in 1925: enteric fever, 84; bowel complaints including dysentery diarrhœa and enteritis 1123 (of whom 82 per cent. were children under three years old) pneumonia and bronchitis, 244 (84 per cent. being of children under three); kidney diseases 197; phthisis and other forms of tuberculosis 208, diseases peculiar to infancy, 520, old age 153; diseases of the heart, 380: syphilis 473 (62 per cent being children under three), and diseases of the nervous system, 335

Barbados enjoys natural and climatic advantages from a health standpoint such as can scarcely be found in any other tropical place. Malaria is unknown there are no extremes of heat or cold, the soil is well drained and the water-supply very good it is, moreover, constantly swept by the trade winds. In these circumstances it is an unusually healthy place of residence for all who are able to secure for themselves freedom from insanitary surroundings. Enteric fever and dysentery are however unfortunately common. The number of cases of enteric notified during the last five years has been: 1921, 3070; 1922, 1084 1923, 735; 1924, 762; 1925, 432 The ordinary type of enteric fever cases is of a mild character A Venereal Disease Clinic was established in 1922 at the General Hospital and it has been attended by steadily increasing numbers The cases treated in 1925 numbered 4317, as against 3083 in 1924 Clinics in other parts of the island are much needed The treatment of lepers at the asylum by the injection of moogrol &c., which was commenced in 1921, was continued during the year, and 15 inmates who had been medically boarded and declared to be cured were discharged from the asylum. In view of the recommendations of the British Empire Leprosy Relief Association for dealing with cases of leprosy, and as a result of a recent visit to the colony of Mr Frank Oldriene (secretary of the Association) a complete change in the outlook with regard to this problem and its treatment has taken place: and it is hoped that sufferers will be induced to come forward for treatment in their earlier stages, when they are more amenable.

Notes, Comments, and Abstracts.

FOREIGN HOSPITALS

ON May 16th Mr Lionel Pearson read a paper before the Royal Institute of British Architects on Recent Developments in Hospital Planning Abroad

His paper was based on visits paid to hospitals in Holland, Denmark, and Sweden and in the Eastern States of America In these countries, he pointed out, the economic effect of the war was not so severe as in England, so that their hospital development has been more continuous He found that European hospitals are rather on the lines adopted in this country—that is to say, the horizontal type of planning is the favourite, and a modified type of the pavilion system still holds its own, but in the United States there is a strong tendency to adopt the vertical type of planning, and the pavilion system is coming to be regarded as old-fashioned Some critics would say that in Europe the comfort of the patient is the first consideration, while in America the efficiency of the staff is put before everything else, but the two points of view seem to be of almost equal importance in hospital planning In all the countries there is a friendly rivalry to produce buildings which are up-to-date from the point of view of medical science and at the same time attractive to the patient And in his journeys he was cheered to find that some of the difficulties that beset hospital architects in this country are apparently universal, for instance he never met a sister who was really satisfied with the accommodation provided for linen, or found a type of window which admitted fresh air without causing a complaint from some patient in the ward

European Hospitals

Mr Pearson then described a series of hospitals which he had seen abroad The characteristics which may be said to be typically Dutch are cheerfulness, cleanliness, and common-sense, with solidity of construction and fresh air and light everywhere The colour schemes are usually very cheerful, and Holland may be said to have very much our ideals in hospital design The tendency in Denmark is to prefer large hospitals built in the pavilion system, the buildings generally being of ample dimensions, well built and well fitted internally The objection to this system is undoubtedly the length of the corridors and the amount of energy expended by the staff in conveying themselves and the food and stores over these considerable distances In addition to this the monotonous repetition of blocks is very depressing architecturally, and the size of the institution must rather eliminate the human element However, there are no doubt very great advantages to be gained in other ways, as the Danes are an extremely practical people and their hospitals have a very high reputation

In Sweden a distinct attempt has been made in hospitals recently built to make the buildings architecturally attractive, as is to be expected in a nation which is so artistically alive The small wards, and to some extent individual sanitation, are approaching the up-to-date American model, but there is a lack of finish in the detail and the constructional methods which falls much behind the best American work Perhaps in the cold northern climate there is not the same necessity for precautions as to ventilation, rounded angles and all the detail considered of such importance in England

American Methods

The industrial expansion in the United States of recent years has led to a great building activity, especially in the big cities, said Mr Pearson, and the number of hospitals which have been built during the last ten years is amazing Fortunately the leading architects are mostly located in New York and Chicago, and as they are most generous in imparting information the task of examining their design is much simplified Whilst in New York he was introduced to Dr Goldwater, the Director of Mount Sinai Hospital, and one of the leading hospital consultants in America, and he came to realise what an important part these consultants play in the hospital business in the States, acting as they do as liaison between the architectural and medical professions The coördination of specialists is one of the successful features of American practice, and the result is that before the building is begun the plans are settled in great detail, and the result is speed and efficiency in the erection

As the great majority of the people of the Eastern States live in cities, the city hospital is the most usual type, and the multi-storeyed hospital is the most popular just now, following the line of the office building, hotel, or apartment house This has led to the vertical type of planning, with the elevator, the laundry chute, and various other labour-saving devices playing a leading part in the construction The long corridors of the European hospital are considered quite out of date, and one American visitor remarked after seeing one of our hospitals that he hoped the staff were fitted with roller skates The concentration which results from the vertical plan certainly simplifies the problem of the heating, lighting, plumbing, and other services There is also the element of what must be called advertisement (for want of a better word), as the high building is never out of sight and out of mind

The Typical American Hospital

Noticeable features of the typical American hospital, said Mr Pearson, are that the entrance is made as attractive as possible, and the waiting-room is furnished like a hotel lounge, and frequently repeated on a smaller scale on the ward floors The inquiry office is usually facing the entrance, and is sometimes in the hall itself, as central heating allows halls and corridors to be used in this way The record room is also near at hand, and the methods of filing and keeping records are justifiably a source of great pride to the superintendents and stenographers The staircase is not a very important feature as a rule, but the elevator lobby makes up for this The kitchen, most frequently placed in the basement and mechanically ventilated, is equipped with every sort of device—electrically heated food conveyors, electric dish-washing machines, mixing machines, orange-squeezers, and the like A cafeteria for the staff is now quite usual, and even the nursing staff are treated to this form of self-service

The wards are now in much smaller units than formerly—16 beds being the maximum, and these are frequently divided by glazed screens into bays of four beds The single-bed ward is becoming increasingly the fashion, though an expert has calculated that only 30 per cent of the patients in an ordinary hospital really require them The nurses' station is either in a glazed enclosure overlooking the ward, or else open to the corridor commanding the approach to the ward The diet kitchen is centrally placed, and it may be noted that the use of refrigerators is general, and "the larder facing north" is not required Opening off the corridor are linen stores, pails and brooms, &c, and all the usual accessories, including the very important flower-room, with a sink and shelves The solarium is either at the end of the ward or a loggia provided on each floor for the use of patients, leaving the ward clear of balconies, and at the top of the building a comfortably furnished sun room is provided with French windows opening on to the "deck" over wards below

The operating block has an operating theatre with floor and walls of pale grey or pale green tiles, or similar material (I saw only one instance of rubber), and the top-light is decidedly out of fashion The reason for this is that the present-day surgeon prefers artificial light, and in one instance 100 cases between 7 A M and 7 P M, in the month of October, showed 69 artificial and 31 natural The anæsthetic room usually opens off the corridor, and is frequently furnished like an ordinary room to avoid the "operation atmosphere"

The plumbing of American hospitals is on rather different lines from what is considered correct in this country The sink room (known as the "utility room") opens off the corridor without a cross-ventilated lobby, while baths and w c's (known as "toilet") often open out of the patients' rooms, and are frequently without windows, depending on mechanical ventilation The pipes are almost always buried in the wall or ceiling, which adds greatly to the smartness and cleanliness of the sanitary rooms All this shows great confidence in modern methods of plumbing, though Mr Pearson suspected that some time there may be trouble ahead

Some Conclusions

After describing nine large hospitals in the United States Mr Pearson reviewed his impressions It is difficult, he said, to arrive at any very definite conclusions from a survey which includes countries of greatly different climate and conditions, but there are some tendencies which are marked everywhere The large ward of 25 or 30 beds seems to be a thing of the past, and smaller units are the rule—16 beds fairly frequent, but 12 beds usually preferred The number of rooms allocated to private and semi-private use is the most marked feature of the present-day planning, though naturally less marked in Europe than in America The individual sanitation which accompanies it in the latter country is perhaps rather overdone, it must mean great expense in the cost of plumbing and fixtures and entail a considerable amount of labour in the running of the hospital, but the provision of hot and cold water in private rooms, and rooms for nurses and staff is of great advantage, as the hotels are finding in all countries

The cross-ventilated lobby is no longer insisted on to the same extent, partly owing to the confidence felt in modern plumbing and partly on the ground of cost The central corridor, on the other hand, found in so many American hospitals, is not a feature of the plan which he would like to see followed, and in this respect the European hospitals appear to have the advantage in point of cheerfulness and health In comparing the vertical and horizontal systems of planning, there are points in favour of each, but on the question of extension (which is of primary importance to hospitals), there is little doubt the horizontal system is easier to handle Mechanical efficiency is found most highly developed in America, but reliance in mechanical means has certain drawbacks, and the case of mechanical ventilation may be given as an instance The saving of labour, however, is so important that attempts in that direction ought to be welcomed

Oil-fuel installations are being adopted increasingly as they result in the saving of labour caused by the handling of coke and ashes, and they also have the advantage of greater cleanliness Finally, the question of architectural interest and beauty is now recognised to be just as important for hospitals as it is for banks, churches, and private residences The general level of hospital design is now very high, and the fact that funds are invariably limited has not been altogether a disadvantage, for it has often resulted in a dignified simplicity which expresses the character and purpose for which the building has been erected

COLONIAL HEALTH REPORTS

BRITISH GUIANA

A REPORT prepared by Mr B H Bayley, acting Assistant Colonial Secretary, on the affairs of this colony for the year 1925 has been issued The estimated population on Dec 31st was 304,412 (154,543 males and 149,869 females) 10,197 births (5276 boys and 4921 girls) were registered during the year The birth-rate was 33 5 per 1000 of the population. The deaths were 7352—24 2 per 1000 The birth- and death-rates per 1000 of the estimated population of each of the several races representing the community were as follows —

Races	Birth-rate per 1000	Death rate per 1000
Europeans (other than Portuguese)	10 7	8 6
Europeans (Portuguese)	24 1	21 1
East Indians	37 3	27 7
Chinese	30 9	16 7
Aborigines	34 8	20 8
Blacks	29 7	23 1
Mixed races	37 7	18 2

The number of children who died under 1 year of age was 1582, or 155 per 1000 births, for 1925, as compared with 1606, or 165 per 1000 births in 1924 A new hospital built by the Demerara Bausite Company on the Demerara River, where the company's plant is situated, was formally opened in May It serves a large number of people, not only at Mackenzie, but also over a wide area of country, and can accommodate 80 patients The Bausite Company carries on a continuous campaign against malaria with satisfactory results and ankylostomiasis has already been eradicated from the company's labouring force

The climate, although warm, is distinctly cooler than that of other British colonies in tropical latitudes and Europeans and other Northern races enjoy consistently good health The mean temperature throughout the year was 80 3° F, the mean maximum being 90° and the mean minimum 69° The heat, which is greatly tempered by cooling breezes from the sea, is felt most from July to October, owing to decreased force of these breezes There are annually two wet seasons, from April to the middle of August and during December and January The annual rainfall for the past 45 years averaged 91 65 inches in Georgetown The rainfall in 1925 was 63 25 inches, as compared with 83 54 in 1924 Sir Cecil Rodwell, K C M G, who succeeded Sir Graeme Thomson, K C B, as Governor, arrived in British Guiana and assumed the government of the colony on Nov 20th

FIJI.

Mr D R Stewart, the acting Colonial Secretary, has furnished a report for the year 1925, in which he states that the general health was satisfactory, apart from an epidemic of typhoid fever in Suva, in which there were 350 cases and 28 deaths Whooping-cough and influenza were prevalent throughout the colony, but there was very little dysentery and no other serious infectious disease Continued progress was made in the campaign against ankylostomiasis This disease is no longer a prevalent cause of debility of the Indian population Practically the whole population has received one treatment, and those living in the wet districts, where it was formerly most prevalent, a second treatment The Makogai Leper Asylum received during the year patients from Samoa, New Zealand, and Niue, and arrangements are complete to receive those from Tonga and the Cook Islands Over 5000 injections of salvarsan were given during the year, and secondary and tertiary yaws are steadily decreasing. The Lautoka hospital with 46 beds for East Indians and nine for Europeans was opened towards the end of the year The vital statistics remain satisfactory, except in so far as the death-rate of the Fijian population is concerned The deaths during the year and the percentages of the respective classes of population were as follows Europeans 37, being 0 90 per cent, Fijians 2012, being 2 2 per cent, Indians 494, being 0 72 per cent, others (excluding Rotumans) 61, being 0 86 per cent. The births were as follows Europeans 68, being 1 66 per cent, Fijians 2856, being 3 22 per cent, Indians 2258, being 3 31 per cent., others (excluding Rotumans) 169, being 2 46 per cent. 1121 marriages were registered, being at the rate of 0 066 of the population During the year 2437 persons arrived in the colony and 2457 departed Arrivals and departures were almost all residents in the colony There was no repatriation steamer for Indians during the year, as it was not found possible to arrange a charter The mean maximum temperature for the year was 82 7, and the mean minimum 70 6 The highest recorded was 91 on Feb 6th, and the lowest 59 8 on July 3rd Rain fell on 217 days during the year, with a total fall of 106 66 inches The greatest fall in 24 hours was 5 84 inches on Sept. 11th. The trade winds were exceptionally light and unreliable during the season There were 21 thunder-storms

The islands of Fiji owe their origin in part to volcanic upheaval. American Methods

The industrial expansion in the United States of recent years has led to a great building activity, especially in the big cities, said Mr Pearson, and the number of hospitals which have been built during the last ten years is amazing Fortunately the leading architects are mostly located in New York and Chicago, and as they are most generous in imparting information the task of examining their design is much simplified Whilst in New York he was introduced to Dr Goldwater, the Director of Mount Sinai Hospital, and one of the leading hospital consultants in America, and he came to realise what an important part these consultants play in the hospital business in the States, acting as they do as liaison between the architectural and medical professions The coördination of specialists is one of the successful features of American practice, and the result is that before the building is begun the plans are settled in great detail, and the result is speed and efficiency in the erection

As the great majority of the people of the Eastern States live in cities, the city hospital is the most usual type, and the multi storeyed hospital is the most popular just now, following the line of the office building, hotel, or apartment house This has led to the vertical type of planning, with the elevator, the laundry chute, and various other labour-saving devices playing a leading part in the construction The long corridors of the European hospital are considered quite out of date, and one American visitor remarked after seeing one of our hospitals that he hoped the staff were fitted with roller skates The concentration which results from the vertical plan certainly simplifies the problem of the heating, lighting, plumbing, and other services There is also the element of what must be called advertisement (for want of a better word), as the high building is never out of sight and out of mind

The Typical American Hospital

Noticeable features of the typical American hospital, said Mr Pearson, are that the entrance is made as attractive as possible, and the waiting-room is furnished like a hotel lounge, and frequently repeated on a smaller scale on the ward floors The inquiry office is usually facing the entrance, and is sometimes in the hall itself, as central heating allows halls and corridors to be used in this way The record room is also near at hand, and the methods of filing and keeping records are justifiably a source of great pride to the superintendents and stenographers The staircase is not a very important feature as a rule, but the elevator-lobby makes up for this The kitchen, most frequently placed in the basement and mechanically ventilated, is equipped with every sort of device—electrically heated food conveyors electric dish-washing machines, mixing machines, orange-squeezers, and the like A cafeteria for the staff is now quite usual, and even the nursing staff are treated to this form of self-service

The wards are now in much smaller units than formerly—16 beds being the maximum, and these are frequently divided by glazed screens into bays of four beds The single-bed ward is becoming increasingly the fashion, though an expert has calculated that only 30 per cent of the patients in an ordinary hospital really require them The nurses' station is either in a glazed enclosure overlooking the ward, or else open to the corridor commanding the approach to the ward The diet kitchen is centrally placed, and it may be noted that the use of refrigerators is general, and "the larder facing north" is not required Opening off the corridor are linen stores, pails and brooms, &c, and all the usual accessories, including the very important flower-room, with a sink and shelves The solarium is either at the end of the ward or a loggia provided on each floor for the use of patients, leaving the ward clear of balconies, and at the top of the building a comfortably furnished sun room is provided with French windows opening on to the "deck" over wards below

The operating block has an operating theatre with floor and walls of pale grey or pale green tiles, or similar material (I saw only one instance of rubber), and the top-light is decidedly out of fashion The reason for this is that the present-day surgeon prefers artificial light, and in one instance 100 cases between 7 A M and 7 P M, in the month of October, showed *69 artificial and 31 natural* The anæsthetic room usually opens off the corridor, and is frequently furnished like an ordinary room to avoid the "operation atmosphere"

The plumbing of American hospitals is on rather different lines from what is considered correct in this country The sink room (known as the "utility room") opens off the corridor without a cross-ventilated lobby, while baths and w c's (known as "toilet") often open out of the patients' rooms, and are frequently without windows, depending on mechanical ventilation The pipes are almost always buried in the wall or ceiling, which adds greatly to the smartness and cleanliness of the sanitary rooms All this shows great confidence in modern methods of plumbing, though Mr Pearson suspected that some time there may be trouble ahead

Some Conclusions

After describing nine large hospitals in the United States Mr Pearson reviewed his impressions It is difficult, he said, to arrive at any very definite conclusions from a survey which includes countries of greatly different climate and conditions, but there are some tendencies which are marked everywhere *The large ward of 25 or 30 beds seems to be a thing of the past* and smaller units are the rule—16 beds fairly frequent, but 12 beds usually preferred The number of rooms allocated to private and semi-private use is the most marked feature of the present-day planning, though naturally less marked in Europe than in America The individual sanitation which accompanies it in the latter country is perhaps rather overdone, it must mean great expense in the cost of plumbing and fixtures and entail a considerable amount of labour in the running of the hospital, but the provision of hot and cold water in private rooms, and rooms for nurses and staff is of great advantage, as the hotels are finding in all countries

The cross-ventilated lobby is no longer insisted on to the same extent, partly owing to the confidence felt in modern plumbing and partly on the ground of cost The central

Chadwick Lecture

ON THE

TEACHING OF INDUSTRIAL MEDICINE.

Delivered in London on May 3rd

BY SIR THOMAS LEGGE, C B E , M D OXF , D P H ,

LATE SENIOR MEDICAL INSPECTOR OF FACTORIES TO THE HOME OFFICE.

[THE lecturer began by referring to a diagram showing the medical services coming into relation with factories and workshops numbering together some 300,000 and employing over 5,000 000 persons Were docks mines, quarries, and railways added, the total would be increased to 7 500,000 Rather more than 300,000 were young persons under 16 years of age. He continued —]

FOUNDATIONS OF INDUSTRIAL MEDICINE

The foundations of industrial medicine were laid about a century ago by first and foremost Charles Turner Thackrah and the members of the first Factory Commission. of which Edwin Chadwick was one As a consequence of the Factory Act of 1833 a certificate was required from a surgeon, there being no birth certification and the age of employment having been limited to 9 years of age, stating that each child had been personally examined, and was of the ordinary strength and appearance of a child at that age Thus arose. perhaps the oldest part-time State medical service (and while thoroughly convinced of the impracticability of a whole-time State medical service I am a strong believer in a part-time one) —namely, that of the certifying factory surgeons Unfortunately, in the next important Factory Act of 1844 the certifying surgeon's duties became stereotyped on a too narrow negative basis Whatever the future of the service—and I do not think it is imperilled under the new Factories Bill—the duties are only likely to be made positive, as they should have been from the first, and somewhat extended , it lies with those who are now medical students, to the number of at least 1500 Thackrah s book on " The Effects of the Principal Arts Trades, and Professions on Health "—the result of clinical observations drawn from the West Riding of Yorkshire and Lancashire —was first published in 1831. Its reception was so successful (how different this from the sale of such a book now !) that it went into a second edition the next year The outstanding merit of his book is that it was written by a clinician and the claim that industrial medicine offers the greatest results for preventive medicine on the clinical side is my main theme here It is a job for the general medical practitioner or consultant and not for the medical officer of health

I believe Thackrah's death, at the age of 37, retarded the progress of industrial medicine and surgery for some 70 years until Whitelegge, as Chief Inspector of Factories and Delepine in Manchester, gave fresh impetus to the subject Had he lived his clinical experience would have emphasised the need of medical supervision in the factory and workshop by practitioners having the necessary knowledge of the home conditions of the workers and treating them for the maladies contracted at their work. While he would have welcomed the operation of the National Health Insurance Act, he would not have been content to see the workpeople streaming when ill from the factory to their panel practitioner and not to see even a trickle from the panel into the factory to try to anticipate intelligently, and check illnesses which otherwise must form claims upon the funds

THE MEDICAL CURRICULUM AND INDUSTRY

While the medical student cannot fail to learn a great deal about the maladies and accidents which strike down the workpeople in common with the general population, little or nothing is done in the medical curriculum to link this knowledge up with their causes arising out of the modern factory system I find myself thus in agreement with Sir George Newman when referring to the examination requirements of the Conjoint Board of the Royal Colleges of Physicians and Surgeons on Public Health he says : " There is a significant absence of all reference to some of the most vital elements of personal and public health "[1] In his list of omissions he mentions health insurance. vital statistics, factory hygiene. industrial poisoning and the duties of the medical practitioner in respect of preventive medicine and his relationship to the sanitary administration of the country Who could trace the vast influence of industry on health in this extract from the syllabus of instruction on public health, unchanged for 20 years, in a first-rate medical school : ' Housing effects on health of overcrowding. vitiated air and occupation," and from that on forensic medicine : " Poisons in their medico-legal aspects "[2] And yet there are 24 lectures given in both public health and forensic medicine to the fourth and fifth year students

The syllabuses might be brought more up to date so that the necessity of thinking twice on industry as affecting health might be awakened by someone competent to impart the information

On this subject the attitude of mind towards labour is very important While naturally all medical and surgical treatment is extraordinarily interesting as between doctor and patient, it is an individual and isolated interest, whereas industrial medicine brings in a host of new factors if only the doors of the imagination are not closed to them as the mind has to visualize the nature of the patient s work the materials used, and the way in which they are used

WHAT THE MEDICAL STUDENT SHOULD LEARN

What then should the medical student learn on the subject before embarking on practice ? First he should have a working knowledge of the 11 forms of *industrial disease and poisoning* which statutorily he will have to notify should he come across any, as he certainly will do, in one of his patients They are poisoning by lead, phosphorus arsenic, mercury, aniline, carbon bisulphide chronic benzene poisoning, anthrax. toxic jaundice. epitheliomatous and chrome ulceration He should know broadly the main industries in which cases of illness and poisoning are likely to arise their main symptoms which he will have learnt at any rate in the case of some of them from the lectures on general medicine or forensic medicine how far they are preventable on general principles which can be applied to them on factory premises and the manner in which they have been affected by the control to which they have been subjected since notification was required. Because medicine has had triumphs in this field as in others And the failures would be pointed out also as so much more can be learnt from them than from the successes In some cases the weal or woe of an industry turns, as in the house painting industry, on the conscientious way in which the obligation to notify lead poisoning is carried out If the cases in this industry fail to diminish, prohibition of the use of white lead paint in the internal painting of buildings will have to be enforced The Secretary of State—he himself has said it

In addition to the 13 notifiable diseases and poisoning. over 20 others are scheduled under the Workmen's Compensation Act Indeed, under this Act is included every industrial disease poisoning, and injury (not being in the nature of an accident) which answers to the test: Is it so specific to the employment that causation by the employment can be recognised in individual cases ? The benefits under this, the Cinderella among Acts of Parliament are none too easy for the workman to obtain unless his medical attendant has made it his duty. in the interests of his patient to find out precisely the necessary procedure Hence some knowledge of the

NEW PREPARATIONS

"HYPOLOID" EPHEDRINE HYDROCHLORIDE.—In addition to "Tabloid" Ephedrine Hydrochloride, gr. ½, which has been available for some months, Messrs. Burroughs Wellcome and Co. are supplying "Hypoloid" Ephedrine Hydrochloride, 0.03 g. (gr. ½ approx.), for hypodermic injection. The "Tabloid" and "Hypoloid" products are of uniform composition and therapeutic activity, and they present the true alkaloid, particular care being taken to exclude pseudo-ephedrine. "Hypoloid" Ephedrine Hydrochloride, 0.03 g., is issued in boxes of ten 1 c.cm. phials.

EATAN.—This preparation, which is to be obtained direct from the distributing agent, Mr. Alfred Dehez, Monument Buildings, London, E.C. 3, has been brought to our attention from the University Hospital in Zurich, where satisfactory results have been obtained from its use. Also, under the description of "Hydrolized Albumen," one of the medical officers of the Charité Hospital, Berlin, has given a favourable account of the use of Eatan and similar evidence has been published in the *Deutsche Medizinische Wochenschrift*. The preparation is described as being the result of "total reduction of animal albumin, blood, connective tissues, bones, joints, blood-forming, internal, secretory and other organs," but the method of preparation is not explained nor is the sort of concrete information given which can be checked by analysis. Granted that the preparation is nutritive and restorative, because this view is supported by a good deal of medical testimony, the demands of scientific therapeutics are not met in the literature which is circulated with the preparation. It is supplied in small bottles at the price of 4*s.* net, and on medical advocacy seems worth trial in cases of debility of varied origin.

IODINE

A RECENT publication by Dr. Kenneth Fraser[1] upholds the importance of a sufficiently iodised diet in preventing a number of conditions besides goitre. His interest in the subject was first aroused by the success of iodine in an apparently hopeless case of rheumatism. He then studied the school-children under his care from the point of view of iodine deficiency, and came to the conclusion that lack of this substance played a part in causing such conditions as boils, chronic septic spots, chronic bronchitis, and debility. He and his colleague Dr. A. H. Towers accordingly administered iodine to children who had failed to respond to the usual lines of tonic treatment, and their results impressed them very much. Dr. Fraser states that in practically every case parents and head teachers reported a marked improvement in health and physique, and a gain in weight, energy, and working capacity. Septic spots and boils vanished, chronic rhinitis cleared up, colds and coughs disappeared and did not recur. In several cases persistent enuresis was stopped. Teachers noted that the children were no longer listless and dull at their work, and a number of backward children were able, when taking iodine, to cope with the work of the standard proper to their age. The best method of administration and the optimum dose of iodine were found to vary. Some children did very well on one iodised sweet or chocolate per week—gr. 1/10 to 1/5 of iodine. On the whole, sweets appeared to give the best and quickest results.

Dr. Fraser is an enthusiast, and research workers may look somewhat askance at his "some hundreds of cases" without recorded controls, and at his rather undiscriminating choice of references to the value of iodine in disorders of all kinds. He is convinced, however, that iodine starvation is the unrecognised cause of much unnecessary ill-health and lack of physical and mental tone, and he regards it as deplorable that iodine-therapy should be associated only with the treatment of goitre, which is, he says, "a side issue, but has become a red herring on the trail of the much greater question—the treatment of iodine starvation cases, irrespective of whether they have goitres or not." Some years ago Hertoghe and Levi[2] described the condition of minor thyroid insufficiency as hypothermia, comprising coldness of the hands and feet, general chilliness, liability to muscular and joint pains, associated with loss of hair, poor appetite, fatigue, and liability to headaches. So common is this picture that it is safe to say that but a small percentage of sufferers have iodine prescribed for them. Dr. S. Barwise, late medical officer of health for Derbyshire, estimated that 10 per cent. of the population of his county were suffering from partial iodine starvation. On the other hand, Dr. W. M. Ash's experience in the same county led him to recommend caution in administration of the drug,[3] and there is good reason to deprecate its wholesale recommendation to the public. It may be hoped that the numerous investigations now being carried out in various parts of the world will lead to a clearer view of the truth. In the meantime Dr. Fraser's thesis calls for the Scot's verdict, "Not proven."

HEALTH PROPAGANDA

THE propagandist in public health often finds it difficult to make clear to lay understanding the objects of research, while it is important that interest should be so aroused that the community will be eager to take advantage of the findings of science. The holding of conferences at which experts, medical and lay, can compare experiences before disseminating their conclusions has been advocated in America, and we have received the Quarterly Bulletin (April, 1927) of the New York Health Demonstrations (Milbank Memorial Fund, 49, Wall-street, New York) which describes in brief such a conference. The movement was sponsored by the United States Public Health Service, the New York State Department of Health, the State Medical Society, the State Charities Aid Association, the New York City Department of Health, the New York Tuberculosis and Health Association, and other bodies with cognate aims, and the main theme of the discussions was the prevention of tuberculosis. Dr. Allen K. Krause, Director of the Kenneth Dows Foundation for Tuberculosis Research at the Johns Hopkins University, referring to the work done in the Cattaraugus County, said it had "taught the shut-in dweller in the remote mountain homestead that consumption need not kill while it had converted the County sanatorium from a domicile of despair into a house of hope, and had helped to stimulate and inspire the country doctor and put at his right hand for service the public health nurse." Dr. Krause supported his words with statistics and with notes made from direct observation and was followed by Dr. Lawrason Brown, Medical Director of the Trudeau Sanatorium, who said that "if all boys and girls during the ages from 10 to 20 could be examined annually, including X ray examination, 90 per cent. of the tuberculosis of early adult life could be prevented." Methods for safeguarding the health of mothers and babies and for providing a public health nursing service for rural areas were among the subjects discussed at the conference, while the brief account of the activities of the Cattaraugus County Health Camp in Allegany State Park, N.Y., suggests many possibilities of conserving child life by means of summer camps conducted on approved hygienic lines. This is certainly a wise way of promoting health propaganda.

THE DELFT YEAST WORKS

WE have received from the Nederlandsche Gist- en Spiritusfabriek an illustrated booklet describing in a popular manner the manufacture of baker's yeast as carried out by this well-known firm at Delft, in Holland. The town has a natural right to the industry as it was a citizen of Delft, Antonie van Leeuwenhoek, who first described the properties of the yeast plant. The N.G. and S.F. factory was started in 1869 by Mr. J. C. van Marken, who combined great business ability with high social ideals. The works, which are now on a very large scale, are up to date, well designed, and famed for the excellence of their products, which include rectified and methylated spirits, and ether for narcosis. The methods of distributing such an unstable product as yeast require to be very efficient and an interesting section is devoted to this subject. The section on social welfare describes the housing estate, with its attractive domestic architecture, the theatre, the school, and the playing fields provided for the staff, who are, we are assured, "one huge family—not a company." No pains have been spared to make the booklet attractive.

DIGBY CHICK

To the Editor of THE LANCET.

SIR,—Your report of the House of Commons proceedings on May 4th, reported in THE LANCET of May 14th, and the heading "Herrings treated with Dye," reminds me to ask some reader of THE LANCET who knows to inform me what is a "Digby Chick"? It has the appearance of a dried unopened bloater of a golden yellow colour. Why is it thus called, and who was Digby, and why a Chick? They are sold in London in some high-class fishmongers.

I am, Sir, yours faithfully,
INQUISITIVE.
May 12th, 1927.

X. Y. Z.—The address of the Industrial Health Education Society, to whose activities we have recently devoted some space (THE LANCET, March 5th, p. 501, and 26th, p. 662), is 89, Millbrae-road, Langside, Glasgow; general secretary, Mr. J. Mackenzie.

[3] THE LANCET, 1926, ii., 1022.

This Institute would have as an indication of the lines to pursue the experience of similar institutions already at work as for example, the Course on Industrial Hygiene in the School of Public Health of Harvard University The lines on which this advanced teaching at Harvard is based are . (1) applied physiology and applied psychiatry, (2) industrial toxicology, (3) industrial health administration, including welfare, (4) workmen's compensation and the legal aspects of industrial disease, and (5) practical industrial medicine

"ETHER" CONVULSIONS

BY S R WILSON, M B, B S LOND, M SC MANCH
F R C S EDIN,
FIRST ANÆSTHETIST, MANCHESTER ROYAL INFIRMARY, LECTURER IN ANÆSTHETICS, MANCHESTER UNIVERSITY

THREE years ago the medical board of the Manchester Royal Infirmary formed an anæsthetic committee for the observation and improvement of the anæsthetic service of the institution I was asked to serve as anæsthetic adviser on this committee and to review with them all deaths or other unusual occurrences attributable to the action of general anæsthetics During the year 1926 manifestations of an entirely new nature came up for consideration, and in October last I commenced an investigation as to the cause of obscure deaths occurring during ether anæsthesia and characterised by general convulsions Towards the end of November I presented a preliminary report to the committee embodying an explanation of these unusual symptoms and suggesting various preventive measures for their elimination The coöperation of the chemical and physiological departments of the Manchester University was also advocated in order that the accuracy of these views might be independently tested A full account of the work done up to date has been presented to the medical board, and further investigations are still being carried on, but the results arrived at are of such great practical importance to all concerned with general anæsthetics that I decided to publish a preliminary report embodying a description of the manifestations, their causes, and prevention In previous years the annual number of anæsthetic deaths occurring in the institution was usually nine or ten These deaths had been easily explicable, and various precautionary measures had been adopted by the board with a view to their reduction or elimination My report for 1926 revealed so great a departure from that of previous years that one cannot do better than quote the introductory part of it

> "From the point of view of anæsthetic casualties, the year 1926 appeared to be singularly fortunate, for in the first six months only one death occurred The patient was suffering from acute appendicitis and the anæsthetic given was ether It was also noted that the patient exhibited convulsions, and the surgeon present was inclined to attribute the condition to respiratory obstruction From July to October, 1926, three more deaths occurred under ether, and in each case definite reference to convulsions was made. In fact, one can best express the state of affairs in the words of the resident surgical officer (Mr Bryce), who concluded his report on the first case he witnessed—I have never heard any explanation as to why these convulsive attacks should occur, nor was there anything in this particular case, either before or during operation, to explain their occurrence"

The committee were of the opinion that the matter needed further explanation, and deputed me to investigate the circumstances and to submit advice as to future action

Clinical Features

In our own hospital four fatal cases were reported, whilst later several non-fatal cases were recorded In one of the fatal cases a post-mortem examination was obtained The descriptions were extremely similar, though noted by different observers It will suffice to describe in detail the fatal case in which a post-mortem examination was made

CASE 3—The patient was admitted into hospital on Sept 15th, 1926 He was a man of 21 who was suffering from acute appendicitis Temp. 103·2° F. Induction was effected with a little ethyl chloride and ether on an "open ether" mask Anæsthesia proceeded normally until a short time after the operation had begun when the patient became cyanosed, although the air-way was quite free Oxygen was then given and the colour improved, but the eyelids were held open in tonic spasm Although the patient was in a state of ordinary surgical anæsthesia twitchings of the eyelids appeared and spread to the face, arms, and legs until the whole body was in a state of generalised clonic convulsions The movements were very severe help being required to hold the patient on the table The patient was slightly cyanosed and all attempts to improve the colour failed The operation was concluded as quickly as possible, the convulsions continuing though somewhat less severely At the end of the operation the breathing became weaker and finally ceased about 50 minutes from the commencement of the anæsthesia The pulse failed shortly afterwards Artificial respiration and cardiac massage were tried but without success

Post-mortem Report—No gross changes were found in the brain, heart, or blood-vessels The lungs were congested and a small amount of frothy fluid exuded on pressure The thymus was enlarged and the lymphoid tissue of the spleen and small intestine pronounced The liver was very adherent to the diaphragm, and dense adhesions were present round the transverse colon and spleen.

The chief points brought out on analysis of the four fatal cases were —

Age.—All were young subjects, the respective ages being 15, 14, 21, and 18 years

Sex.—Three were males, one a female

Disease—Three were very definite cases of acute appendicitis with pyrexia The other was a case of gas gangrene following a double compound fracture of the leg

Onset—In all cases the induction of anæsthesia appears to have been uneventful. The convulsions appeared after the actual operation had been in progress several minutes

Duration—Death occurred in from 40 to 50 minutes from the commencement of the anæsthetic

Mode of Death—Convulsions, followed by respiratory stoppage with slight cyanosis, later heart failure

Other Remarks—In one instance the administrator resorted to chloroform to check the convulsions This appeared to precipitate a fatal issue The case of compound fracture of the leg followed by gas gangrene is of interest, in that ether was given when the fracture was first set, and nothing unusual was noted throughout the administration Three days later amputation was decided upon owing to the supervention of gas gangrene, ether was again given and this time convulsions and death supervened

Administrators were then requested to report any non-fatal cases showing convulsions, and to preserve the ether used for analysis Five detailed reports were received All were males between 4 and 29 years of age and were suffering from acute appendicitis with abscess, with one exception This latter was a middle-aged man suffering from piles In all these cases the patient was freely ventilated with oxygen directly the convulsions appeared, and the anæsthetic discontinued or a fresh supply of ether used

Discussion.

A detailed analysis of these cases revealed *two* points of the utmost importance

1 These cases did not correspond to any known form of anæsthetic collapse

2 That the position of ether as a practically safe anæsthetic was seriously assailed

The two immediate problems which presented themselves for solution were · (*a*) What was the cause of death? (*b*) What was the explanation of the convulsions

The Cause of Death—Sudden death during anæsthesia can only be due to failure of one or other of the three systems—respiratory, cardiac, and nervous—whose continuous activity is necessary for life All the reports presented agreed that there was no primary failure of respiration or circulation The heart was always the last to give out and the degree of cyanosis was never excessive The mode of death and the early appearance of convulsions point to the nervous system as the one essentially affected working of the Act is a matter of urgency for the newly qualified practitioner. Neither his own certificate nor any certificate under the National Health Insurance Act will help the patient.

Further, the medical man is much more likely to be called on to give *evidence at an inquest* on a case due to the effects of poisonous dust, gases, or fumes than in a murder case, and the nature of the principal ones—carbon monoxide from blast furnaces, power gas and in coal mines, sulphuretted hydrogen gas, nitrous fumes, and the like—should be stressed in the teaching of forensic medicine. The dramatic side of "gassing" cases, and the means of defence against them, as, e.g., in mine rescue work, should not be excluded from the medical curriculum. I would emphasise the extraordinarily human side of the applications of physiology, engineering, and chemistry in the protection of the industrial population. The sheet-anchor, for instance, for the protection of workers against injurious dust, gases, and fumes is locally applied exhaust ventilation as near as possible to their point of origin, and against vitiated air from aggregation of persons general mechanical ventilation by means of extraction fans. The disadvantages of plenum systems of ventilation in this respect, not only for factories but for schools and public buildings, also ought to be insisted on. This system invites the air into a room and then having in its course stirred the dust up leaves it to find its way out as best it can. Extraction fans give the air a directional movement. An immense field of educational work is required to impress on factory employees Hill's dictum that moving air and not the atmosphere of the reptile-house of the Zoological Gardens—his description, not mine—is the proper one for human beings to live in.

How many medical men know that unless the employer has done everything (and everything means a good deal) the workman can do next to nothing to protect himself against the risks of his trade? No dangerous industry can be made safe to-day without bringing to bear upon it an influence or influences external to the workman—that is to say, conditions over which he can exercise no control. Examples of industries, highly dangerous 25 years ago, which have been made either safe or very much safer than they were by such means, are (1) the lucifer match industry by the substitution of sesquisulphide of phosphorus for yellow phosphorus (achieved by the Berne Convention regulations having proved a failure); (2) the manufacture of white lead paint owing to the discovery of the greater affinity of white lead for oil than for water, so that now a suspension of white lead in water is converted into oil paint in automatic closed-in machines without the creation of any dust; (3) the pottery industry through the discovery of the late Sir Edward Thorpe, the Government chemist, that carbonate of lead can be combined with silica, &c., in such proportion as to form a glaze practically insoluble in the human body; (4) disinfection of anthrax-infected wool, as in the Government wool-disinfecting station in Liverpool, and the treatment of anthrax by serum.

Examples of influences dependent on the worker's will to use them and, therefore, useful up to a point—but no remedy—are respirators, gloves, washing accommodation, overalls, and waterproof sandpaper to try to stop the dust in dry rubbing down of painted surfaces.

Lastly, I think the medical student should receive a picture of the *causes underlying so-called industrial unrest*. And this subject can be made very interesting by tracing industry through the industrial revolution down to modern times. In doing this he could be made to realise how this country passed through a dark page in its social history, the memory of which and the fear of a repetition is at the back of the minds of all trade-unionists. This subject at first sight might be thought a little outside my sphere, but the psychology of the worker and of the employer are both very prominent to-day and must remain so for many years to come. This aspect of industrial medicine is the basis of the work of the Institute of Industrial Psychology and of that of the Industrial Fatigue Research Board, a department of the Medical Research Council. The newly qualified practitioner in an industrial area may well have to treat his patient not only for a particular malady, but also for the social and industrial conditions which memory and auto-suggestion have conjured up. And by virtue of the healing art he practises no one can unconsciously influence both employer and employed so well if the right attitude towards labour has been grounded in the medical man during his student days. He stands in a privileged position and his influence is incalculable.

[This subject was illustrated by slides of workshop conditions under the craft guilds during the industrial revolution, and of the best modern construction; also by slides of Constantin Meunier's bronzes of the miner, the glass-blower, the tanner, &c., and a picture of industrial fatigue by Degas.]

THE RÔLE OF THE M.O.H.

Is anything more than I have described necessary in the teaching of industrial hygiene under the new regulations of the General Medical Council for the Diploma of Public Health where, in *Part II.*, it is linked up with maternity and child welfare service, school medical service, venereal disease service, tuberculosis service, and inspection and control of food as essential subjects for instruction? These, except industrial hygiene, are part of the business of the local medical officer of health, and it would almost appear as though the General Medical Council intended that the M.O.H. should become the mandarin to deal with industrial medicine despite the limitations of his office for such a task. His high position as the authority on housing makes it desirable that he should, in addition to the matters I have enumerated, know about factory construction, drainage, sanitation, water-supply, cloakroom accommodation, and be in touch with the welfare department if there is one. But let him keep hands off the clinical side inside the factory. This clinical side in the hands of the general practitioner might well be linked up with the other local public health services, but not be entirely run by the local authority. The medical officer of health has a definite rôle to protect the health of the individuals affected by influences under the control of the local authority. He has no opportunity of studying the effects of industry on living persons nor could it be made to fit in with his other duties, nor can he be expected to be responsible for the health of the population caused by matters outside the control of the local authority. A medical officer of health could not survey usefully the effects of industry from the standpoint only of his particular area. Factory administration would lose its value if handed over to officers responsible to local authorities and not to a central department.

It would never do for the medical officer of health to be called the certifying surgeon (or the "appointed doctor," as the Factories Bill has it) in the same manner as he is now designated the school medical officer. On the whole, therefore, seeing how much more than a knowledge of sanitation should be required of the medical man in the factory, I do not think the training in industrial medicine for the D.P.H. requires to be much in advance of that I should like to see given to the medical student.

A CENTRAL INSTITUTE OF HYGIENE.

There still remains, as suggested in the report of the Post-Graduate Medical Committee, the Central Institute of Hygiene to develop in the future research work and advanced teaching in all branches of preventive medicine, including as one of them industrial medicine and hygiene. Here the "distinctively high proficiency, scientific and practical," which is aimed at by the General Medical Council would be obtained by those who are going to make this their life work—the full-time industrial physicians and surgeons and a few others

3 Acetaldehyde and "peroxide" have been definitely demonstrated to be present and afford adequate explanation of the anomalous symptoms

4 The chemical properties of aldehyde are such as would account for these effects, for it is a powerful reducing agent, and would tend to cell asphyxia, and the subsequent formation of acetic acid would increase the H-ion concentration of the tissue fluids and equally favour convulsions The aldehyde appears to volatilise first and the peroxide seems to favour aldehyde formation

5 The detrimental effects of these impurities are most pronounced in patients already suffering from toxæmias

6 In our experience the impurities were present in the ether on delivery, and were increased in amount by existing methods of ether administration

7 It is possible that in some instances of deaths under ether in cases of acute appendicitis these toxic agents have contributed to a fatal result without the actual occurrence of convulsions Also that post-anæsthetic vomiting is greatly intensified by their presence for, since a pure ether has been in use, there has been a striking reduction in this symptom

8 It is not clear as to why these impurities should apparently have only appeared in toxic amounts since the beginning of 1926 Prof Lapworth suggests there may have been some change in the method of manufacture I am not aware of any such change, and am of the opinion that the change probably lies in the spirit used in manufacture

9 The question of ether purity requires further investigation, and strict standard tests are required for application to all ethers supplied for the purpose of general anæsthesia

In the meantime we have adopted certain precautionary measures (1) Only pure ethers are to be used (2) The ether in use is periodically tested by ourselves (3) Exposure to light and air have been eliminated until actually in use (4) All stale ether from the operating theatres is discarded and sent to the dispensary to be used for other purposes, such as the making of ether soap (5) I have designed a modification of our ether vapour bottles (Shipway), in which amber glass is used to protect the ether from the theatre lights, and the metal tube which projects below the level of the ether is replaced by bone or ivory (6) All cases showing convulsions are to be reported, whether fatal or not, and the ether in use to be preserved for analysis Should convulsions occur the patient should be promptly ventilated with oxygen containing 5 per cent carbon dioxide, and if more anæsthetic is required a fresh batch of ether is to be used

In view of the importance of the condition a circular letter was sent to 24 anæsthetists in London and the provinces Twenty-one replies were received, and I take the opportunity of thanking those who did so Analysis of these letters revealed that five observers had direct knowledge of the manifestations, three observers had heard of them, three observers had noted convulsions in recognised epileptic patients, but all had recovered, and ten observers had no knowledge of the condition Dr Z Mennell attributed the condition to deep etherisation and hyperoxygenation Dr F E Shipway was inclined to suspect the presence of impurities in the ether Dr H G Dodd suggested an association with modern methods of etherisation Dr C Hadfield wrote me very fully on behalf of the Joint Anæsthetics Committee of the Medical Research Council and Royal Society of Medicine They considered the matter one of considerable importance and requiring investigation At the time of writing they possessed no adequate explanation. It will be noticed that our observations more or less harmonise these various views

In conclusion, whilst we await more detailed observations from the scientific side in the public interest, a thorough reinvestigation of the question of ether purity in relation to general anæsthesia is eminently desirable

CHOLECYSTOGRAPHY.

BY PETER G McEVEDY, M B LOND, F R C S ENG,
HONORARY SURGEON, ANCOATS HOSPITAL, MANCHESTER,
AND
JESSIE E SHERET, M B, B S DURH, D M R & E CAMB,
ASSISTANT RADIOLOGIST TO THE HOSPITAL

THE last few years have witnessed an intensive study of the liver and biliary tract, and probably the most important discovery from the practical point of view has been that of cholecystography Graham and Cole[1] published the first paper on cholecystography in 1924 Since then published results have proved that this is now an essential method in the investigation of the dyspepsias Graham[2] and his associates now obtain a diagnostic accuracy of 97 per cent by the intravenous method

The substance that has been most generally used has been sodium tetraiodophenolphthalein, but Graham now finds that its isomeric compound phenoltetraiodophthalein gives equally good shadows in smaller doses, so that the chance of toxic effects is lessened With the substances in use at present there are still many debatable points There is not general agreement as to the method of administration or as to the value of certain points in the interpretation of the radiograms The dye is administered either intravenously or orally, and Graham, after a large experience, advocates the intravenous method. The advantages of this are that it gives much denser radiograms than the oral method, and that it is more certain in its action A known quantity of dye that is excreted almost exclusively by the liver is introduced into the circulation at a known time.

The disadvantages are · (1) as in all intravenous methods constant care must always be exercised in the preparation of the substance used and in its administration, (2) with the substances at present in use there is a slight danger of thrombophlebitis, (3) severe reactions may occur on rare occasions as evidenced by cases reported where the symptoms have been alarming

The advantages of the oral method are that it can be given with perfect safety, and it is not necessary for the patient to be in hospital The administration is simple, time-saving, and free from accidental dangers The disadvantages are that the amount absorbed from the intestinal tract is not known for certainty, the rate of the absorption is variable, and certain mild toxic symptoms may occur In our series several patients complained of nausea In only two cases did actual vomiting occur, in one of these the capsules were vomited As the radiograms are not as dense as those obtained by the intravenous method, their interpretation is more difficult and the percentage of positive and negative shadows of gall-stones is lower

Graham states that cholecystography is really a means of studying the function of the gall-bladder rather than the exact pathological lesions present, and that the only two known functions of the gall-bladder are the regulation of the pressure within the biliary tract and the concentration of the contained bile Regulation of the pressure is shown by changes in size of the gall-bladder shadow, indicating distensibility and contractility, and the power of concentration is shown by the increasing density of the shadow

We have analysed the results obtained by cholecystography in a hundred consecutive cases controlled by operation Many of the cases were operated upon for disease of organs other than the gall-bladder, but only those cases are included in which the gall-bladder was inspected at the operation

Explanation of the Convulsions—Every single observer gave a clear and definite account of the occurrence of convulsions preceding a fatal issue They started in the eyelids and face and gradually spread all over the body, and were not associated with any respiratory or circulatory embarrassment

The other points brought out on analysis of the reports were · (*a*) all the patients were young subjects, (*b*) all the fatal cases and most of the non-fatal ones were already in a state of toxæmia (acute appendicitis and gas gangrene)

The constancy of the convulsions points to the nervous system as the one primarily concerned in these unusual deaths Convulsions really signify shortage of oxygen or irritation of the nerve-cells of the central nervous system Whilst such oxygen shortage may result from both respiratory and cardiac failure, in the cases in question there was no evidence of inefficiency of these systems Local oxygen shortage might be due to gross cerebral lesions—such as embolism—but against this is the fact that the convulsions were absolutely generalised, and the post-mortem examination made revealed no naked-eye change in the nervous system or elsewhere which could adequately explain the condition

In view of these facts I concluded that death was due to a *poison acting on the central nervous system*, such poison rendering the nerve-cells incapable of utilising oxygen

Impurities in Ether

It was clear that there was a definite relationship between the administration of ether and these effects, and yet pure ether could not be held accountable, having been in general clinical use for a matter of 70 years without any previous mention of such symptoms It appeared probable that the poisonous effects were due to the presence of impurities, and that such impurities had either recently arisen in manufactured ether or were increased in amount by modern methods of administration or both The former supposition was not altogether unlikely, seeing that between 1919 and 1921 various papers appeared in which it was contended that pure ether was not an anæsthetic and a tendency developed to use impure ethers on this account Whilst such a statement was disproved by the fact that ether had been used over 50 years with satisfaction, and also by the scientific work of Dale, King, and von Leeuwen, the impression still persisted amongst practical anæsthetists

The common impurities liable to be present in anæsthetic ethers are acetaldehyde, "peroxide," ethyl sulphide, ketones, and alcohols The first three of these have been shown by Wesley Bourne to be toxic agents if present to the extent of ½ per cent or more The first two would be likely to interfere with cell oxidation, whilst ethyl sulphide causes enteritis The presence of these impurities in anæsthetic ether might be due to (1) imperfect purification of the original ether, (2) gradual development of the impurities with age, (3) exposure of ether to light and air, (4) contact of ether with actinic light and oxygen.

I concluded that the unfavourable symptoms were due to the *presence in the ether of acetaldehyde or peroxide or both*, and that these impurities would be greatly increased in old-standing samples and particularly if the ether were exposed to the actinic rays of an operating theatre lamp and oxygen bubbled through it, as in a Shipway apparatus Whilst a normal person might survive such poisoning, a patient already partially poisoned from acute toxæmia might easily succumb

With the help of Mr Butchers, our senior pharmacist, rough tests were made which appeared to substantiate these views I also tested spectroscopically the glass storage bottles and the glass of the storage cupboards The amber glass bottles were efficient, but the glass of the storage cupboards, though apparently almost black, transmitted the full spectrum, especially the actinic rays It was also realised that a bottle might remain unused for an indefinite period, but this has been rectified by dating each bottle on delivery to the theatre If these deductions were correct confirmation would most probably be obtained from investigation of the contents of the ether in the Shipway apparatus, for (*a*) old ether is usually allowed to remain in them, (*b*) they are constantly under the influence of the actinic lights of the operating theatre, (*c*) oxygen is being continually bubbled through them

All these conditions would favour the development of aldehyde and peroxide I examined the Shipway apparatus in all the theatres, and naked-eye observation revealed marked corrosion and oxidation of the metal tube The contents were taken away for analysis

In order to test the validity of these deductions we decided to submit samples for chemical investigation to the Chemical Department of the Manchester University and the laboratory of British Drug Houses, which was kindly placed at our disposal No information was divulged, but various samples were put up in similar bottles labelled with identification marks known only to myself Reports as to purity were asked for

The first batch for analysis comprised hospital methylated ether from stock (S), hospital methylated ether from theatre (T), contents of Shipway apparatus from one of the theatres (4), a guaranteed pure ether (B D H) taken at random (5), ether from drop bottle in case of convulsions (6)

These were investigated by Prof Lapworth and his assistant, Mr Robinson, in the Chemical Department of the Manchester University A summary of their report follows —

> " Both S and T contain conspicuous amounts of acetaldehyde, and give a definite deposit of the double compound with sodium bisulphite Such appreciable quantities of aldehyde should be barred The samples also give definite tests as regards ' peroxide ' There is very little free alcohol and methyl alcohol present, but we feel the quantities are too small to prove dangerous To summarise your samples we may say No 5 is in a class by itself Traces of impurities are so slight as to be practically indetectable S T 4 and 6 all give positive results as regards acetaldehyde and peroxide and we would place them as follows S T 6 4 Further tests have confirmed these initial observations, and in two cases of convulsions that recovered the ether was loaded with these impurities "

We also took advantage of the offer of British Drug Houses to make use of their laboratory, for they had for some years interested themselves in the question of pure ether and were especially familiar with the " peroxide " test The numbered samples submitted to them comprised specimens of our methylated ether from stock, from theatre stock, from an ordinary Shipway apparatus, and a sample I had personally prepared by bubbling oxygen through ether in a Shipway apparatus whilst exposed to the artificial light of the theatre for two hours They reported that samples from stock and theatre showed 15 times the peroxide which should be present in a more or less pure ether, samples from the Shipway bottle showed 20 times as much, whilst the artificially prepared sample showed 25 times as much The aldehydes were in excess of any commercial ether they had previously examined Dr A D MacDonald and myself have verified that acetaldehyde has a very definite toxic action in animals

The work is still being continued, and it is my hope that there will be further communications from the departments concerned, but the results up to date afford so striking a confirmation of one's initial deductions that, with the full approval of our committee, I decided to bring them to the general notice of the profession and of those interested in ether purity

Conclusions

1 The convulsions referred to represent an entirely new complication of ether anæsthesia

2 The convulsions are toxic in origin and due to the presence of impurities in the ether

examination Sosman, Whittaker, and Adson[5] state that, although olive oil caused emptying of the gall-bladder in dogs in man it had no effect, and that no effect was produced by exercise They showed, experimentally, that an intact sphincter of Oddi is necessary to obtain a normal cholecystogram

Density of the Radiogram

The power of concentration possessed by the gall-bladder is shown by the density of the shadows, the variations in the power of concentrating the dye are difficult to interpret, and the deductions to be drawn must be founded on experience The diagnostic value of this point is still unsettled but as a single fact it is not sufficient to warrant a definite diagnosis Certainly failure to concentrate is of little value in the diagnosis of a pathological gall-bladder when the dye is given orally In the five cases in which the shadows were faint, the gall-bladder was normal in three and pathological in two at operation We now consider poor concentration simply as an indication that the test should be repeated orally or preferably intravenously

The late appearance of a shadow with the oral method is apparently of no diagnostic value In one case the shadow was first seen 15 hours after the dye was given, three hours later normal concentration had taken place, and at operation a normal gall-bladder was found

The Pathological Gall-bladder

The chief difficulty seems to be to decide when a gall-bladder is pathological. The type of bile in the gall-bladder may be of assistance in arriving at a diagnosis, but it is not uncommon to find concentrated bile in a definitely pathological gall-bladder The appearance of the gall-bladder at operation may, on rare occasions, be misleading In one case the gall-bladder looked perfectly normal, but was found to contain a few minute stones and was definitely abnormal on pathological examination. Some gall-bladders appear normal even after removal, but are found to be abnormal on pathological examination How far is the pathologist's report of a diseased gall-bladder to be accepted as a justification for the removal of an apparently innocent-looking gall-bladder? What percentage of normal-looking gall-bladders would be pathological on microscopic examination? These questions will always influence the statistics on diagnosis by cholecystography Certainly the symptoms are no indication as to the stage of the disease In two cases where gall-stones were found at operation no symptoms could be attributed to the diseased gall-bladder.

Conclusions.

1 Cholecystography after the oral administration of sodium tetraiodophenolphthalein gave a correct diagnosis in 92 per cent of cases controlled by operation 2 A faint shadow of the gall-bladder after giving the dye on one occasion does not warrant the diagnosis of a pathological gall-bladder 3 Early cases of cholecystitis may give normal shadows 4 Occasionally a normal gall-bladder may fail to give a shadow 5 In out-patients only the results of those showing a normal shadow or stones are to be accepted The others need further investigation as in-patients

ACUTE INFECTIVE OSTEOMYELITIS

By BASIL HUGHES, D S O, B Sc LOND,
M.B CAMB, F R C S ENG,
SURGEON, BRADFORD MUNICIPAL GENERAL HOSPITAL, HON SURGEON, BRADFORD CHILDREN'S HOSPITAL, HON ASST SURGEON, BRADFORD ROYAL INFIRMARY.

ALTHOUGH histologically identical, there are two types of acute osteomyelitis which differ essentially in their origin, clinical course, prognosis, and treatment These may be classified (*a*) osteomyelitis traumatica, (*b*) osteomyelitis symptomatica

(*a*) *Osteomyelitis Traumatica*

This occurs as the result of trauma, the infection reaching the bone from without and the organisms being foreign to the individual It is seen in connexion with street accidents severe crushes, and the like, and it was seen to good advantage during the Great War It was during the war that its pathology became better understood and its present-day treatment founded In connexion with it the following points are important: (1) the extent of damage to the bone and soft parts (2) the extent of hæmorrhage occasioned, (3) the degree of shock, (4) the general condition of the individual at the time of the accident, (5) the virulency of the infection.

Of all the long bones injuries involving the femur are the most serious If the general condition of the individual prior to the accident is poor, and if considerable hæmorrhage and shock have occurred, it is amazing how rapidly a general septicæmia can develop Infection under these conditions is productive of septic infarcts in the lungs spleen and other deep organs and suppurative pericarditis is not an uncommon complication Septic infarction of the skin (fixation abscess) is extremely rare, whereas pyothorax, following upon infarction of the lung, is not uncommon Cultures taken from the pleural exudation have given invariably a luxuriant growth of organisms It may seem strange that organs like the spleen lungs, and kidneys which are so richly supplied with blood, should be singled out for infective infarction but it is understood when we consider that the patient is suddenly infected with foreign organisms against which he possesses no immediate immunity at a time when shock is extreme and when a considerable hæmorrhage has taken place Further, damaged tissues under these conditions allow of rapid bacterial proliferation locally

Treatment is (1) resuscitative, (2) operative Resuscitation must always precede operation for it is useless to operate upon any patient during an interval of shock In every instance in which shock is pronounced and hæmorrhage has occurred direct blood transfusion should be undertaken This must be carried out at the earliest possible moment after the accident It is a useless expedient if left until a virulent septicæmia has established itself. Heat should be applied, subcutaneous saline and stimulants in the form of warm drinks given, and a careful watch maintained for a rising blood pressure and a reactionary hæmorrhage The fractured limb meantime must be immobilised and kept elevated. Operative treatment aims at a complete excision of all bruised and devitalised tissue with removal of the damaged portion of the bone This is carried out preferably under open ether anæsthesia While resecting the damaged bone the periosteum as far as possible must be spared The limb is now replaced on a Thomas splint and a Carrel Dakin dressing applied Provided the wound remains clean, a bone-graft may be inserted to replace the resected portion. The wound need not be absolutely sterile for this undertaking, but it should be free of streptococci and spores, whose absence can be determined by repeated examination of the wound discharges Antitetanic serum should always be given together with polyvalent antistreptococcic serum An autogenous vaccine is often of use, because the patient is without an initial immunity to the infection

Preparation and Technique

Sodium tetraiodophenolphthalein was used in all cases, and the following was the method of administration.

On the day previous to examination the patient was kept on light diet until 9 P.M when a meal, from which proteins were largely omitted, was given, followed by the tetraiodophenolphthalein The amount of the dye given was that recommended by Graham—i e , 0 06 g per kilo of body-weight The patient was radiographed the following day at 9 A M , at 1 P M , and again at 5 P M The capsules used in the examination were those supplied by W Martindale

While in many of our earlier cases undissolved capsules were seen in the colon, they were absent from this series of cases It is probably due to the fact that the coating of the capsules at times failed to dissolve that a large percentage of error in diagnosis occurred during our early cases

There is a small chance of the normal gall-bladder not filling when the dye is given orally This occurred in two of our cases We think that, with the present method of preparing the capsules, this is less likely to occur Still there is no doubt that this failure of the normal gall-bladder to give a shadow in a small percentage of cases is one of the disadvantages of the oral method However, we think that if the gall-bladder fails to fill, and there are no symptoms pointing to gall-bladder disease, then the test should be repeated before a definite diagnosis is made In very fat patients failure to obtain a shadow of the gall-bladder is of little diagnostic value

Interpretation of Radiograms

In the interpretation of the cholecystograms we accepted as normal those in which the gall-bladder cast a dense shadow without shadows of calculi. Cases were diagnosed as pathological in which (1) the gall-bladder did not fill, (2) positive or negative shadows of gall-stones were present, (3) the gall-bladder shadow was faint, and there was no concentration

Analysis of Cases

In this series of 100 cases the X ray diagnosis was correct in 89 per cent of cases that were normal at operation, and in 94 per cent of cases that were pathological at operation

The gall-bladder appeared normal at operation in 47 Of these, 42 were diagnosed as normal and 5 as pathological by cholecystography Of the five that were thought to be pathological, three filled but the shadows remained faint, and in two cases there were no shadows In the two cases in which the gall-bladder failed to fill there was evidently some failure of absorption of the dye In one case the gall-bladder filled normally at a subsequent examination, and in the other the gall-bladder was removed as the symptoms were suggestive of cholecystitis, but it appeared normal on macroscopic examination, contained concentrated bile, and the microscopic evidence of slight cholecystitis did not justify the X ray findings

In 53 cases the gall-bladder was pathological at operation The operative findings were —

Chronic cholecystitis with calculi	48
„ „ without calculi	2
Dilated gall bladder secondary to carcinoma of the pancreas	2
Carcinoma of the gall bladder	1

Of these, 50 cases were diagnosed as pathological and three as normal by cholecystography The X ray findings were as follows —

No shadow of the gall-bladder	42
Faint shadows of the gall bladder	2
Positive shadows of gall stones	3
Negative „ „	2
Diffuse mottling of the gall bladder	1
Normal shadows „ ,	3

In the three cases that were diagnosed as normal the gall-bladder filled, concentrated, and emptied normally At operation the gall-bladder in each case was thin-walled and bluish and contained concentrated bile, but showed a small amount of subperitoneal fat at the fundus in two, and careful palpation revealed a few small calculi The microscopic examination showed definite evidence of chronic inflammation It is very unlikely that the intravenous method would help in the diagnosis of these early cases, but where the stones are larger and the gall-bladder is still functioning normally it is more likely to show the calculi as shadows It is quite evident that the gall-bladder may be functioning normally, as judged by cholecystography, and yet may be definitely pathological

In one case the gall-bladder was faintly outlined before administration of the dye, filled and concentrated well after the dye was given, and at operation appeared to be normal A small percentage of gall-bladders show on the films taken before giving the dye, but the part played by disease in causing a gall-bladder to give a shadow has yet to be settled The amount the fundus of the gall-bladder protrudes beyond the edge of the liver is certainly a factor in deciding these shadows

Wilkie and Illingworth[3] report a case in which the correct diagnosis of a pathological gall-bladder was made from the deformity of the cholecystogram Hurst[4] states that cholecystography is a very useful means of confirming the presence of gall-bladder tenderness, and of deciding if the tenderness is confined to the visualized gall-bladder When the dye is given orally, although the radiograms may show quite dense shadows, we have not found screen examination to be very satisfactory

Cases with Jaundice

Contrary to what has been stated, we have found cholecystography to be of value in cases with jaundice In three cases of catarrhal jaundice, not included in the above series, the gall-bladder filled and concentrated well The diagnosis was confirmed by the subsequent course of these cases Likewise, in a case of biliary cirrhosis with marked jaundice, and in a case with jaundice due to secondary deposits in the liver, the gall-bladder filled normally In cases with obstruction of the common bile-duct the gall-bladder invariably fails to fill with the dye When the obstruction is due to carcinoma of the common bile-duct or of the pancreas, the gall-bladder, although still functioning, is so distended with thick tarry bile that not sufficient dye is carried to the gall-bladder to give a shadow

Emptying of the Gall-bladder

Various substances have been used to cause emptying of the gall-bladder Food of any description will cause the gall-bladder shadow to become less dense Fats act more quickly than proteins or carbohydrates We have tried various substances, and have found olive oil to be very effective, 2 oz of olive oil at times causes a dense shadow to disappear in 30 to 50 minutes If the gall-bladder gives a shadow at the second examination we now give 2 oz of olive oil and make the third examination one hour later However, as with all other substances we have tried, the time taken to cause the shadow to disappear has varied widely in different cases This is particularly marked with pituitary extract From the emptying power of these substances, so far, we have not been able to draw any deductions that are reliable in making a diagnosis Their use in estimating the pathological condition of the gall-bladder has yet to be worked out

We have found that strenuous exercise has, at times, a definite effect in emptying the gall-bladder For this reason we have advised out-patients to take as little exercise as possible between the time of administration of the dye and the completion of the four deaths were associated with infection of this bone, two involving the upper diaphysis and the hip-joint, and two the lower diaphysis, one involving the knee-joint Of the remaining 24 cases, five involved the proximal site of the diaphysis of the tibia, and ten were confined to the distal site Thus 31 out of 40 cases involved the bones of the lower extremity—i e , 75 per cent The remaining nine cases involved the humerus in five, the radius in two, and the ribs in two

Osteomyelitis Traumatica	*Osteomyelitis Symptomatica*
1 Brought about by trauma and infection from without	1 A symptom of an existing septicæmia
2 No initial immunity to organisms of infection	2 Infecting organisms are patient's own organisms, consequently there is an existing degree of immunity
3 Septic infarction of vital organs and absence of fixation abscesses in the subcutaneous tissues	3 Absence of deep infarction and presence of superficial fixation abscesses
4 Septicæmia is secondary	4 Septicæmia is primary
5 Early operative treatment essential	5 Conservative measures demanded
6 Shock and hæmorrhage necessitating resuscitation prior to operation	6 Absence of shock and primary hæmorrhage

AN ATTEMPT TO ISOLATE *BACTERIUM PNEUMOSINTES* FROM PATIENTS SUFFERING FROM INFLUENZA

BY G S WILSON, M D , M R C P , D P H LOND ,
LECTURER IN BACTERIOLOGY IN THE UNIVERSITY OF MANCHESTER , ASSISTANT DIRECTOR OF PUBLIC HEALTH LABORATORY, MANCHESTER

Olitsky and Gates[1] and Gates[2] have described the isolation of a minute, anaerobic, Gram-negative cocco-bacillus, capable of passing through a Berkefeld N or V candle, from the nasopharyngeal washings of patients suffering from clinical influenza The nasopharyngeal washings, which as a rule proved virulent only during the first 36 hours of the disease, gave rise on intratracheal injection into rabbits to a syndrome of fever, mononuclear leucopenia, and conjunctivitis , when killed, usually after two days, the animals showed pulmonary lesions consisting of emphysema, œdema, and hæmorrhages The organism was cultivated directly from the filtered nasopharyngeal washings of influenza patients, but more frequently and with greater success from the ground-up lungs of rabbits that had been injected with these washings Primary cultures were obtained in Smith-Noguchi medium, but later the organism was cultivated anaerobically on blood agar plates, in coli-broth, and on certain other media Suitable suspensions of the organism, which they call *Bacterium pneumosintes*, were agglutinated, generally to a titre of 1–10, by the serum of a number of patients that had recovered from influenza from ten days to five months previously The findings of Olitsky and Gates have been partially confirmed by a number of other workers (for references see Gates [2]), but the evidence that this organism is in any way causally connected with the production of influenza in human beings is unsatisfactory

Influenza in Manchester, 1927

During the first quarter of the year there was an outbreak of influenza in this country To illustrate the progress of the disease in Manchester the influenzal deaths and reported cases of influenzal pneumonia are given as follows

1927. Week ending—		Influenza deaths	Influenzal pneumonia cases
Jan	8	1	8
"	15	9	6
"	22	8	7
"	29	8	9
Feb	5	7	9
"	12	13	28
"	19	31	47
Feb	26	88	110
March	5	70	96
"	12	58	58
"	19	26	18
"	26	9	17
April	2	10	9
"	9	6	11

It will be seen that the height of the epidemic was reached during the last fortnight of February and the first fortnight of March The usual symptoms in typical cases of the disease were chilliness, fever, headache, prostration, pain in the back and limbs, suffusion of the conjunctivæ, sore-throat, and later tracheitis After 3 to 14 days or so the attack subsided, leaving the patient weak and listless Numerous abortive cases lasting only 24 or 48 hours occurred

In this laboratory about half of the staff was attacked Most of the cases occurred during the first three weeks of February, so that by the time influenza was rising to its maximum in the city as a whole the laboratory epidemic was practically over

Experimental Work.

During the progress of the epidemic an attempt was made to cultivate *B pneumosintes* from the nasopharynx of influenza patients

The technique adopted was as closely similar as possible to that described by Olitsky and Gates Briefly, it was as follows —

After preliminary cleansing of the mouth, each nostril was washed out with 25 c cm of sterile saline, the fluid being returned through the mouth and collected in a sterile bottle The washings were shaken with glass beads for 20 minutes, and 1 5 to 3 0 c cm were injected intratracheally under ether anæsthesia into young rabbits weighing 1000 to 1500 g After two days the rabbit was killed by one blow on the back of the neck, and under strictly aseptic precautions the lungs were removed to a sterile Petri dish After examination of the macroscopic appearances, one of them was cut into fragments, ground up with sterile sand in a mortar or a Griffith's tube, and suspended in a small quantity of saline , 1 c cm of this suspension was then seeded into one or more tubes of Smith-Noguchi medium, and aerobic cultures were made on to blood-agar and Fildes agar slopes If the lungs appeared at all suspicious, 2 0 to 3 c cm of the suspension were injected intratracheally into a fresh rabbit In addition portions of the lungs were reserved for section, and portions were transferred to 50 per cent glycerol for further study if necessary

The Smith-Noguchi medium was made up with pure untreated ascitic fluid to which 1 per cent of dextrose had been added , a large piece of rabbit's kidney was placed at the bottom of the tube, and the whole was covered with a layer of vaseline 1 c cm deep , the tube was further sealed with a paraffined cork After two or three days in the incubator anaerobic conditions were established, as was shown by the progressive decolorisation from below upwards of methylene-blue added to a control tube In order to obtain a satisfactory degree of anaerobiosis, all tubes, therefore, were incubated for three days before inoculation

The pure ascitic fluid had a reaction of pH 8 2, but that of the finished medium was about pH 7 4—a reaction which, according to Olitsky and Gates,[3] is very favourable for the growth of *B pneumosintes*

Direct cultivation of the nasopharyngeal washings was attempted on only two patients , prior to seeding into Smith-Noguchi medium the washings were filtered either through a Mandler or a Chamberland L 2 candle (Berkefeld N and V candles were unobtainable) , 1 c cm. of the filtrate was used as the inoculum In the animal experiments with one exception, in which an L 2 candle was used, all cultures were made from unfiltered lung suspensions

The Smith-Noguchi tubes were incubated at 37° C for ten days Subcultures were then made into fresh tubes of the same medium, and on to two lots of blood-agar or Fildes agar slopes, one lot of which was incubated aerobically and one lot anaerobically in a modified McIntosh and Fildes jar. Anaerobic subcultures were also put up in coli-broth * This procedure was repeated twice after intervening periods of ten days Altogether, therefore, four Smith-Noguchi tubes were inoculated in series, and subcultures made from each into blood-agar or Fildes agar, and coli-broth

One of Olitsky and Gates's original strains of *B pneumosintes* was kindly sent to us by Dr David Thomson This organism grew very well under anaerobic conditions in Smith-Noguchi medium, on blood-agar, and Fildes agar slopes, and in coli-broth We inoculated it on to every batch of medium prepared, and incubated these cultures along with

---

* *Coli* broth was prepared by growing a strain of *B coli* in 1 per cent dextrose broth , as soon as the first sign of turbidity appeared, the flask was removed from the incubator and steamed for half an hour In this medium under anaerobic conditions *B pneumosintes* formed a moderate to dense turbidity in seven days

(b) *Osteomyelitis Symptomatica*

This is most commonly a disease of children and young adults The onset, which is preceded by an interval of malaise and pyrexia, is often associated with a sore-throat or occurs during convalescence from one of the exanthems, notably scarlet fever and measles Speaking from a careful study of over 40 cases in children, both bacteriological and clinical, there is abundant evidence to prove that the disease *is only a symptom of a general septicæmia* The bones most commonly singled out for infection are the femur and tibia, both weight-bearing bones, and so more subject to jars and knocks The distal ends of the diaphyses of these bones are the common sites for the initiation of the infection

Pathologically, the disease consists in an acute infection of both the bone-marrow and the compact bone surrounding it The infection may become localised and thus analogous to an ordinary acute abscess elsewhere, or it may become diffuse and involve the entire medullary cavity, in which case it is an acute cellulitic condition The inflammatory process spreads outwards along the Haversian canals and reaches the periosteum, which strips easily from the bone, but does not readily lose its vitality The extent to which the periosteum so strips is an accurate indication of the involvement of the medulla and compact bone Not only does the periosteum retain its vitality, but the endosteum also, important facts to be borne in mind when considering the subject of treatment Osteomyelitis that has become localised will often settle down without active surgical treatment, indeed the condition often passes unrecognised and is treated as rheumatism In such circumstances a small abscess cavity containing organisms of low virulence remains and becomes surrounded by dense bone (Brodie's abscess) The favourite sites for these abscesses are the distal ends of the femoral and tibial diaphyses In future debilitating illnesses these abscesses are prone to become active and may give rise to a diffuse osteomyelitis, or by bursting into a neighbouring joint they may set up an acute septic arthritis

Pain at the site of infection, usually the knee or ankle, is the early symptom The pain may early leave the neighbourhood of infection and migrate to the region of other joints, which may become hot, red, and tender, hence the condition at first is very apt to be confounded with acute rheumatism Later pus forms, which may find an exit from the bone, and either come to the surface or burrow in between the muscles of the limb Should the complete medullary cavity be involved in a cellulitis, the whole limb is exceedingly painful, and constitutional symptoms are more severe Light percussion over *the bone involved causes intense agony to the patient.* From the very beginning symptoms of septicæmia are present The temperature is high and remittent, rigors occur, and the patient is often delirious Common accompaniments are a coarse tremor and picking the nose and face until they are raw Sordes may be present on the lips and teeth, but the tongue is usually clean and the patient takes liquid nourishment well •

Subcutaneous pressure abscesses (fixation abscesses) are common and a bacteriological investigation of their contents gives a clue to the prognosis Thus (1) sterility of the abscess with well-staining leucocytes *is* of good prognosis, (2) *mild infection* calls for a guarded prognosis, (3) virile infection with degenerate leucocytes is of bad prognosis Remarkable, and in strong contrast with the traumatic type, is the absence of deep infarction It occurred in one of my cases only (the spleen), and this case is of such interest in showing the difficulty of early diagnosis that I will relate it briefly

R P, male, aged 10 years, after a period of malaise was seized with pain in his left knee which became swollen and tender The pain left the knee and affected several other joints in turn The temperature was high and the condition was treated as acute rheumatism, which it closely mimicked On the fourth day the patient complained of acute pain in the abdomen, the tenderness limiting itself to the lower right abdominal quadrant At this stage I saw the patient with Dr Frank Anderson, of Stanningley We diagnosed acute appendicitis, and although there was some swelling just above the left knee joint a laparotomy was undertaken There was a considerable quantity of turbid flakey fluid free in the peritoneal cavity but the appendix was not at fault The spleen, however, was enlarged A septic splenic infarct accounted for the abdominal condition. An exploring needle revealed pus just above the knee-joint and an incision proved the condition to be osteomyelitis starting in the lower end of the diaphysis Despite every care the knee-joint became infected The patient, owing to the pain and his general infection, started to go down hill Amputation through the middle third of the thigh was undertaken, and pus was observed to come from the bone-stump After a protracted convalescence the patient recovered and is alive and well to-day The temperature settled only some weeks after amputation, and numerous skin abscesses appeared showing bacteriologically scanty growth on agar *The last skin abscess to appear was sterile* The infection was streptococcal

The natural tendency of symptomatic osteomyelitis is towards recovery Pyrexia may continue for weeks or months, and the patient may become reduced to skin and bone, still the tendency is towards recovery It has often amazed me how a child can stand up to and fight a septicæmia of this kind, and it is a condition therefore in which hope should never be lost

In this series of cases the following were of good omen (1) ability to take nourishment and digest it, (2) sterility of fixation abscesses, (3) the ready healing of fixation abscesses after bursting, (4) a clear mentality and ability to sleep peacefully, (5) absence of albumin in the urine

Of bad omen are (1) hæmorrhage from the vessels around the neighbouring joint, (2) virile infection of fixation abscesses, (3) sluggish indolent appearance of the tissues after the abscess has burst, (4) delirium, anorexia, and inability to sleep, (5) presence of albumin in the urine

Treatment is that of *septicæmia* The less that is done surgically the better If pus has found an exit from the bone, I have been content to make an incision for its evacuation and have gone no farther If the inflammation is confined within the medullary cavity and there is no exit (diffuse osteomyelitis), an incision down to the bone with removal of a limited portion of its compact layer is all that is necessary Under no consideration should the medullary cavity be curetted, because valuable and necessary tissue is removed and the endosteum is destroyed Curetting is analogous to removing the subcutaneous tissue in an acute cellulitic condition of the soft parts

Amputation is called for (1) when uncontrollable hæmorrhage occurs in the region of a joint; (2) when a large joint, specially the knee, becomes infected and *pain is militating against the patient's* chances of recovery I performed amputation in only two of my cases for the above-mentioned reasons The result was an immediate improvement I do not think, however, that the improvement came about as a result of removing infected tissues It was rather the result of removal of the pain of an infected knee-joint in one case and the arrest of hæmorrhage in the other Further, the removal of a limb under these conditions means a saving of energy to the defensive mechanism of the body generally In view of our knowledge of the pathology, resection of the infected bone for symptomatic osteomyelitis is unsound *treatment* This is one of the main points of difference between the *symptomatic* and the traumatic type Good food of a nourishing type, and patients can take and digest it, plenty of fluids, and occasional small doses of calomel are the main essentials

Summary

Of 40 cases of the symptomatic type on which this article is based, there have been four deaths—that is, a mortality of 10 per cent Twenty-five cases occurred in males and 15 in females, or the disease in this series is nearly twice as common in the male sex. Of the bones infected, the femur was involved in 16, and all four deaths were associated with infection of this bone, two involving the upper diaphysis and the hip-joint, and two the lower diaphysis, one involving the knee-joint Of the remaining 24 cases, five involved the proximal site of the diaphysis of the tibia, and ten were confined to the distal site Thus 31 out of 40 cases involved the bones of the lower extremity—i e , 75 per cent The remaining nine cases involved the humerus in five, the radius in two, and the ribs in two

Osteomyelitis Traumatica	*Osteomyelitis Symptomatica*
1 Brought about by trauma and infection from without	1 A symptom of an existing septicæmia
2 No initial immunity to organisms of infection	2 Infecting organisms are patient's own organisms consequently there is an existing degree of immunity
3 Septic infarction of vital organs and absence of fixation abscesses in the subcutaneous tissues	3 Absence of deep infarction and presence of superficial fixation abscesses
4 Septicæmia is secondary	4 Septicæmia is primary
5 Early operative treatment essential	5 Conservative measures demanded
6 Shock and hæmorrhage necessitating resuscitation prior to operation	6 Absence of shock and primary hæmorrhage

AN ATTEMPT TO ISOLATE *BACTERIUM PNEUMOSINTES* FROM PATIENTS SUFFERING FROM INFLUENZA

By G S WILSON, M D , M R C P , D P H LOND ,
LECTURER IN BACTERIOLOGY IN THE UNIVERSITY OF MANCHESTER , ASSISTANT DIRECTOR OF PUBLIC HEALTH LABORATORY, MANCHESTER

Olitsky and Gates [1] and Gates [2] have described the isolation of a minute, anaerobic, Gram-negative cocco-bacillus, capable of passing through a Berkefeld N or V candle, from the nasopharyngeal washings of patients suffering from clinical influenza. The nasopharyngeal washings, which as a rule proved virulent only during the first 36 hours of the disease, gave rise on intratracheal injection into rabbits to a syndrome of fever, mononuclear leucopenia, and conjunctivitis , when killed, usually after two days, the animals showed pulmonary lesions consisting of emphysema, œdema, and hæmorrhages The organism was cultivated directly from the filtered nasopharyngeal washings of influenza patients, but more frequently and with greater success from the ground-up lungs of rabbits that had been injected with these washings Primary cultures were obtained in Smith-Noguchi medium, but later the organism was cultivated anaerobically on blood-agar plates in coli-broth, and on certain other media Suitable suspensions of the organism, which they call *Bacterium pneumosintes*, were agglutinated, generally to a titre of 1–10, by the serum of a number of patients that had recovered from influenza from ten days to five months previously The findings of Olitsky and Gates have been partially confirmed by a number of other workers (for references see Gates [2]), but the evidence that this organism is in any way causally connected with the production of influenza in human beings is unsatisfactory

Influenza in Manchester, 1927

During the first quarter of the year there was an outbreak of influenza in this country To illustrate the progress of the disease in Manchester the influenzal deaths and reported cases of influenzal pneumonia are given as follows

1927. Week ending—	Influenza deaths	Influenzal pneumonia cases	1927 Week ending—	Influenza deaths	Influenzal pneumonia cases
Jan 8	4	8	Feb 26	88	110
„ 15	9	6	March 5	70	96
„ 22	8	7	„ 12	58	58
„ 29	8	9	„ 19	26	18
Feb 5	7	9	„ 26	9	17
„ 12	13	28	April 2	10	9
„ 19	34	47	„ 9	6	11

It will be seen that the height of the epidemic was reached during the last fortnight of February and the first fortnight of March The usual symptoms in typical cases of the disease were chilliness, fever, headache, prostration, pain in the back and limbs, suffusion of the conjunctivæ, sore-throat, and later tracheitis After 3 to 14 days or so the attack subsided, leaving the patient weak and listless Numerous abortive cases lasting only 24 or 48 hours occurred

In this laboratory about half of the staff was attacked Most of the cases occurred during the first three weeks of February, so that by the time influenza was rising to its maximum in the city as a whole the laboratory epidemic was practically over

Experimental Work

During the progress of the epidemic an attempt was made to cultivate *B pneumosintes* from the nasopharynx of influenza patients

The technique adopted was as closely similar as possible to that described by Olitsky and Gates. Briefly, it was as follows .—

After preliminary cleansing of the mouth, each nostril was washed out with 25 c cm of sterile saline, the fluid being returned through the mouth and collected in a sterile bottle The washings were shaken with glass beads for 20 minutes, and 1 5 to 3 0 c cm were injected intratracheally under ether anæsthesia into young rabbits weighing 1000 to 1500 g After two days the rabbit was killed by one blow on the back of the neck, and under strictly aseptic precautions the lungs were removed to a sterile Petri dish After examination of the macroscopic appearances, one of them was cut into fragments, ground up with sterile sand in a mortar or a Griffith's tube, and suspended in a small quantity of saline , 1 c cm of this suspension was then seeded into one or more tubes of Smith-Noguchi medium, and aerobic cultures were made on to blood-agar and Fildes agar slopes If the lungs appeared at all suspicious, 2 0 to 3 c cm of the suspension were injected intratracheally into a fresh rabbit In addition portions of the lungs were reserved for section, and portions were transferred to 50 per cent glycerol for further study if necessary

The Smith-Noguchi medium was made up with pure untreated ascitic fluid to which 1 per cent of dextrose had been added , a large piece of rabbit's kidney was placed at the bottom of the tube, and the whole was covered with a layer of vaseline 1 c cm deep , the tube was further sealed with a paraffined cork After two or three days in the incubator anaerobic conditions were established, as was shown by the progressive decolorisation from below upwards of methylene-blue added to a control tube In order to obtain a satisfactory degree of anaerobiosis, all tubes, therefore, were incubated for three days before inoculation

The pure ascitic fluid had a reaction of pH 8 2, but that of the finished medium was about pH 7 4—a reaction which, according to Olitsky and Gates,[3] is very favourable for the growth of *B pneumosintes*

Direct cultivation of the nasopharyngeal washings was attempted on only two patients , prior to seeding into Smith-Noguchi medium the washings were filtered either through a Mandler or a Chamberland L 2 candle (Berkefeld N and V candles were unobtainable) , 1 c cm of the filtrate was used as the inoculum In the animal experiments with one exception, in which an L 2 candle was used, all cultures were made from unfiltered lung suspensions

The Smith-Noguchi tubes were incubated at 37° C for ten days Subcultures were then made into fresh tubes of the same medium, and on to two lots of blood-agar or Fildes agar slopes, one lot of which was incubated aerobically and one lot anaerobically in a modified McIntosh and Fildes jar Anaerobic subcultures were also put up in coli-broth * This procedure was repeated twice after intervening periods of ten days Altogether, therefore, four Smith-Noguchi tubes were inoculated in series, and subcultures made from each into blood-agar or Fildes agar, and coli-broth

One of Olitsky and Gates's original strains of *B pneumosintes* was kindly sent to us by Dr David Thomson This organism grew very well under anaerobic conditions in Smith-Noguchi medium, on blood-agar, and Fildes agar slopes, and in coli-broth We inoculated it on to every batch of medium prepared, and incubated these cultures along with those from our experimental material to make sure that the conditions for growth were satisfactory Every one of these control cultures grew excellently

---

* Coli broth was prepared by growing a strain of *B coli* in 1 per cent dextrose broth , as soon as the first sign of turbidity appeared the flask was removed from the incubator and steamed for half an hour In this medium under anaerobic conditions *B pneumosintes* formed a moderate to dense turbidity in seven days

Seven patients were examined, all in the first 24 hours of the disease On four occasions the injections were made into rabbits within an hour of washing out the nasopharynx, on two occasions (patients 5 and 7) between four and seven hours, and on one occasion (patient 3) not till the washings had stood in the ice-chest overnight

Results

Before giving in detail the bacteriological examination of each patient, a few general remarks are necessary First of all we have paid very little attention to changes occurring in the Smith-Noguchi cultures Every one of these tubes—even uninoculated control tubes—showed a varying degree of turbidity on incubation We were unable to convince ourselves that this was in any way dependent on the multiplication of a living micro-organism This seems to have been the experience of other workers [4] Secondly, after examining these tubes microscopically, we came to the conclusion that staining methods were unreliable for demonstrating organisms as small as *B pneumosintes* It was not possible with certainty to distinguish between uninoculated control tubes and tubes in which a known strain of this organism was growing Unless actual colonies can be obtained on a solid medium, or a marked turbidity in a clear fluid medium such as coli-broth, we consider that the demonstration of this organism has not been satisfactorily accomplished

Olitsky and Gates laid stress on the development of conjunctivitis, a rise of temperature, and a mononuclear leucopenia in inoculated rabbits, and on the changes in the lungs at post-mortem examination None of our rabbits showed conjunctivitis Leucocyte counts were made only on the first two rabbits, both of these showed a well-marked mononuclear leucopenia. Counts on the other animals were rendered impossible owing to the pressure of routine work Temperature charts were kept for some of the animals, but in view of Purdy's work [5] it did not appear that any but marked variations could be regarded as significant It may be pointed out that in the protocols given by Olitsky and Gates the rise of temperature was rarely more than 1° C The lung lesions described by Olitsky and Gates were never observed Most of the rabbits showed marked congestion of the trachea, and a few scattered hæmorrhages beneath the pleura But these did not appear different from those observed in normal rabbits killed by a blow on the back of the neck [6] In two or three rabbits a localised fullness of the lung was noticed macroscopically, and in these a second rabbit passage was performed—always without result

Though realising the importance of studying the reaction of the rabbits to injection, we felt it still more important to concentrate our efforts on the actual cultivation of *B pneumosintes* In these efforts we failed completely, from not a single patient did we succeed in isolating this organism

CASE 1—Feb 1st Laboratory attendant Typical attack lasting four days Pneumococcus and Pfeiffer bacillus recovered on direct culture from N P (nasopharyngeal) washings Two rabbits inoculated in series from N P washings All cultures, aerobic and anaerobic, sterile

CASE 2—Feb 18th Clerk Typical attack lasting 14 days, similar to that in 1918 *β*-hæmolytic streptococcus, pneumococcus, and Pfeiffer's bacillus recovered on direct culture from mouth washings N P washings filtered through L 2 candle and seeded into S N (Smith-Noguchi) medium All cultures sterile N P washings injected into a rabbit. Lung suspension filtered through L 2 candle, all cultures sterile Second rabbit inoculated in series Lung suspension not filtered All cultures sterile

CASE 3—Feb 22nd Student at laboratory Typical attack lasting four days One rabbit inoculated Aerobic cultures sterile Staphylococcus grown from third subculture in S N medium Cultures discarded

CASE 4—Feb 22nd Laboratory staff. Typical attack, lasting a week Pneumococcus and Pfeiffer's bacillus recovered on direct culture from N P washings Two rabbits inoculated in series From S N cultures of first rabbit a pneumococcus was isolated All cultures from second rabbit proved sterile

CASE 5—Feb 23rd Housewife Typical attack lasting five days One rabbit inoculated All cultures sterile

CASE 6—Feb 25th Laboratory staff Typical attack lasting nine days One rabbit inoculated All cultures sterile

CASE 7—March 2nd Nurse Typical attack lasting five days N P washings filtered, and seeded into S N medium All cultures sterile Unfiltered N P washings injected into one rabbit Diplo-streptococci isolated from first S N tube Cultures discarded.

Agglutination Experiments

Olitsky and Gates demonstrated the presence of agglutinins—generally at a titre of 1/10—in the serum of 17 out of 19 persons who had recovered from clinical influenza ten days to five months previously

We prepared a serum against a known strain of *B pneumosintes* by repeated injections of a rabbit with washed, killed organisms from a culture in coli-broth The agglutinating antigen was made up in the way described by Olitsky and Gates,[7] using Northrop and de Kruif's buffer solution at pH 6 3 Experiment showed, however, that a more agglutinable antigen could be obtained by adding 0 25 per cent formolised saline to coli-broth cultures and heating to 60° C for half an hour, or by suspending the centrifuged and washed bacilli in 0 5 per cent phenolised saline

We tested the serum of 35 persons in the laboratory against a formolised broth culture of *B pneumosintes* Of these 16 had suffered from clinical influenza 4 to 11 weeks previously, the remaining 19 had not had influenza for at least one year The tests were read after 18 hours' incubation at 55° C None of the sera agglutinated in dilutions from 1/2 to 1/64 The control rabbit serum agglutinated at 1/128 It must be remembered that only one strain of *B pneumosintes* was used Since we do not know whether all strains of this organism are antigenically homogeneous, it is impossible as the result of these experiments to assert more than that antibodies were absent from the patients' sera to this particular strain

Summary

(1) The nasopharyngeal washings of seven patients within the first 24 hours of a typical attack of influenza have been examined by the method of Olitsky and Gates From not a single patient did we succeed in isolating *B pneumosintes*

(2) The serum of 16 persons who had recently suffered from influenza was tested against a *B pneumosintes* antigen, along with the serum of 19 control persons No agglutination was observed —even in a dilution of 1/2

(3) Though we have carefully followed the technique of Olitsky and Gates we have completely failed to confirm their observations on the presence of *B pneumosintes* in the nasopharynx of patients in the early stages of influenza

In conclusion we would express our thanks to Drs G D Dawson, F R Ferguson, and Dr H Harrison for assisting us in the collection of material, to Dr P P Laidlaw for the loan of suitable filter candles; and to Prof W W C Topley for his help with some of the animal experiments

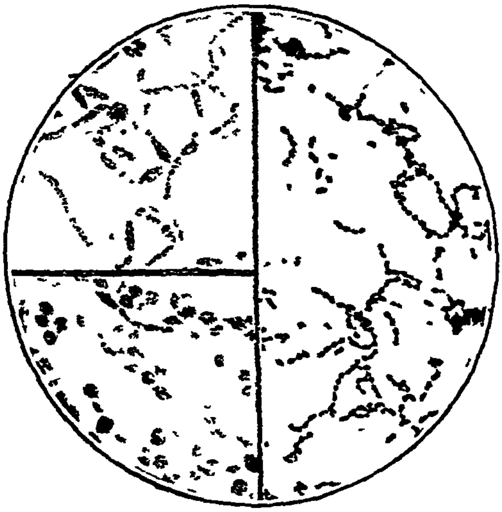
INVESTIGATIONS ON THE ÆTIOLOGY OF INFLUENZA.

BY DAVID THOMSON O B E , M B , CH.B EDIN D.P H CAMB ,
DIRECTOR ,
AND
ROBERT THOMSON M.B , CH B EDIN ,
PATHOLOGIST, PICKETT THOMSON RESEARCH LABORATORY,
ST PAUL'S HOSPITAL, LONDON

IN a letter to THE LANCET of Jan 29th 1927, the authors pointed out that the true cause of influenza was not yet definitely settled At first it was believed to be due to the so-called influenza bacillus discovered by Pfeiffer (1892) During the great Pan-epidemic of 1918 however this belief began to be doubted for although Pfeiffer's bacillus was found in a fairly high percentage of cases of influenza investigations showed that it was often present also in a high percentage of normal persons even during periods when the disease was not prevalent Several observers obtained Pfeiffer's bacillus in from 50 to 85 per cent of normal individuals It was also pointed out that in diseases like measles and scarlet fever, the percentage of findings of Pfeiffer's bacillus became greatly increased The belief therefore began to grow that this organism was more a secondary invader than the true cause of the malady Failures in attempts to produce influenza in human volunteers by injecting pure recently isolated cultures of Pfeiffer's bacillus into the nose and throat further tended to confirm this belief

FIG 1

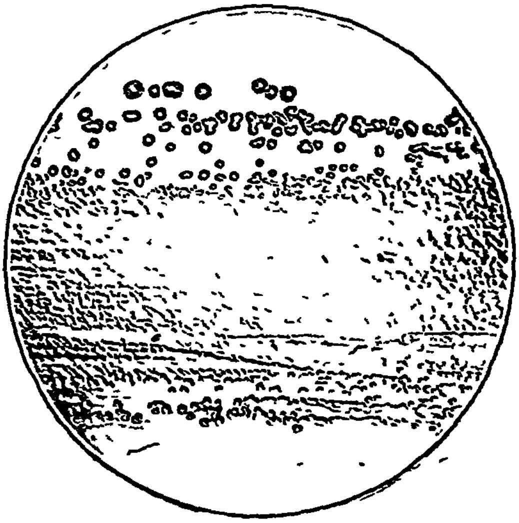


Pleomorphic streptococcus isolated from the blood of one of the authors during an attack of influenza On left 24 hours' test, agar, aerobic, × 1700 On right Broth culture, × 1700

The research worker therefore began to seek for some other cause It has always been agreed that streptococci play an important part in the disease as secondary invaders but several workers now began to suspect that a certain streptoccocus might be the primary cause Others sought for filter-passing organisms, and finally Olitsky and Gates, at the Rockefeller Institute, attempted to prove that *Bacterium pneumosintes* was the true causal organism

The writers have done a certain amount of work on *B pneumosintes*, and after finding a satisfactory medium succeeded in isolating this organism after great difficulty from about three cases of influenza during the year 1925 Somewhat similar bacteria appeared, however, to be present at times in non-influenza cases In December, 1926, as already mentioned in THE LANCET, Jan 29th, 1927, one of us contracted suddenly rather a severe attack of influenza and blood was drawn off from a vein within eight hours of the commencement of the attack and inoculated into culture tubes suitable for the growth of *B pneumosintes*, a streptococcus, however, appeared instead This streptococcus was simultaneously isolated from the interior of the nose

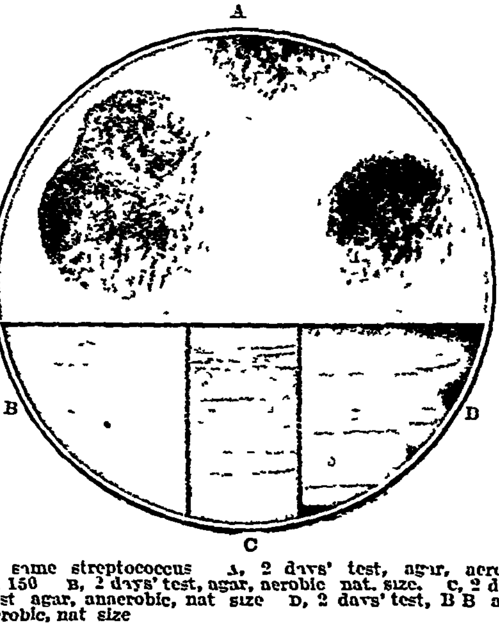
FIG 2.



The same streptococcus Two days' test, agar, aerobic, × 20

The evidence appeared therefore to point to this streptococcus as the primary cause of this apparently true influenzal attack, and it seemed hardly likely that it could already be a secondary invader, as the attack had only commenced eight hours previously

FIG. 3



The same streptococcus A, 2 days' test, agar, aerobic × 150 B, 2 days' test, agar, aerobic nat. size. C, 2 days' test agar, anaerobic, nat size D, 2 days' test, B B agar, aerobic, nat size

After the appearance of our letter in THE LANCET we received a letter from Dr Crookshank, pointing out that a pleomorphic organism had been found in influenza cases by Dr Donaldson himself and several other workers Later, two letters appeared in THE LANCET of February, 1927, one by Dr Donaldson and the other by Dr Fearis, both drawing attention to further references on this subject

During the past two years the authors have been making a special study of the streptococcus group by keeping a careful microphotographic record of all species isolated During this time about 100 varieties have been carefully studied and recorded photographically

Seven photographs of each variety have been taken, amounting in all to a total of about 700 photographs We have worked on this matter in conjunction with Dr Warren Crowe, who simultaneously studied a large number of the varieties on his specialised chocolate blood medium, recording the appearance of the colonies thereon by reflected light After many years of research by his special methods, Warren Crowe is also satisfied that there are well over 100 varieties of streptococci existing on the mucous surface of the body, and that as many as ten or more varieties may be found in one individual Neither Warren Crowe nor ourselves had previously investigated the streptococcal flora of the respiratory tract in influenza, so that none of the 100 varieties recorded by us had come from influenza cases

Now the interesting fact is, that this pleomorphic *streptococcus which we had isolated from the blood* and nose of the case of influenza did not coincide with any of the 100 varieties of streptococci already mentioned in our collection This fact made us still the more suspicious that this new streptococcus might be the possible cause of the disease We sent a culture of this organism to Warren Crowe for his opinion, and after investigation he gave the following statement "Your blood streptococcus is undoubtedly different from any in my catalogue" Since his catalogue comprises over 100 varieties which did not come from influenza cases, this is further reason for our suspicion These indeed were the facts which led us to write our letter to The Lancet of Jan 29th Since that date we have made a thorough photographic record of this pleomorphic streptococcus found simultaneously in the blood and in the nose in the earliest stage of influenza (See Plate I, Figs 1–3) It will be noted that this streptococcus is pleomorphic only when grown aerobically on solid media In broth culture it is a small streptococcus occurring in moderately long chains and without any suggestion of pleomorphic forms It grows rather better anaerobically than aerobically On boiled blood agar, aerobically, it bleaches the medium for some distance around to a definite yellow colour When first isolated in broth media it grew rather feebly, later it grew profusely, leaving a fairly copious white deposit with a moderately clear supernatant fluid It shakes up into an emulsion which contains granular flakes When grown in Hiss's serum water, containing various sugars, it produces after 3 to 11 days acid and clot in glucose, maltose, galactose, saccharose, lactose, dextrin, inulin, salicin, and raffinose It dose not ferment mannite It produces slight acidity but no clot in litmus milk It does not liquefy gelatin It is insoluble in bile After it had been subcultured for two months, half a cubic centimetre of a strong emulsion of the live germ injected intravenously into rabbits produced no harm The pleomorphic streptococcus from the blood and from the nose were found to be identical in every respect *It shows no evidence of being definitely hæmolytic*

Further cases of influenza were now investigated Boiled blood-agar plates were inoculated from the sputum and from throat swabs Colonies of streptococci which bleached the blood were picked off and investigated As many as three varieties of bleaching streptococci were found as a rule in each case In each of four cases of influenza thus examined a pleomorphic streptococcus corresponding exactly to the above description was found In addition, some five further varieties of bleaching streptococci were found which were not pleomorphic, and which gave different sugar reactions We failed to find this pleomorphic streptococcus in two normal individuals who had not had influenza for a year or more Perhaps *the most interesting fact in this investigation* is that the patient (one of ourselves), from whose blood and nose the pleomorphic streptococcus had been isolated in December, had *another mild attack* of influenza two months later, and the same pleomorphic streptococcus was found to be abundantly present in the sputum It is just possible, therefore, that this organism had been present in the respiratory tract for the two months following the first attack

Some months hence a further investigation will be made again to ascertain if this organism is still present We have written this paper, not with any claim that we have discovered the causal organism of influenza, but simply to encourage further researches along these lines

A NOTE ON THE
PREPARATION AND PROPERTIES OF A
FEMALE SEXUAL HORMONE
(MENFORMON) IN WATER SOLUBLE FORM

By Prof ERNST LAQUEUR,
Dr P C HART, and Dr. S E de JONGH
(*From the Pharmaco-Therapeutic Laboratory, University of Amsterdam*)

In The Lancet of May 14th, 1927, Dr E. Dickens, Prof E C Dodds. and Mr D J T Brinkworth describe a process for the manufacture of a water-soluble preparation of the ovarian hormone It may be of interest therefore to summarise here some of our own recent investigations in this field, which have obviously remained more or less unknown in England

Messrs Dickens, Dodds, and Brinkworth state that they have been unable to obtain the hormone in a water-soluble form by means of our so-called water procedure We do not know why they failed,[1] but we draw attention to the fact that during last year *many thousands of units have been prepared* by means of this technique at the Organon Works (Oss, Holland) and the Degewop Works (Berlin) among other places These have been standardised and their strength has been controlled by us We also sent such watery preparations amongst others to Dr E Allen and Dr E A Doisy to compare our standardisations, both investigators found even a slightly higher content of units than we did We take this opportunity of pointing out that the greatest advance in this field is due to American investigators, first and foremost to Drs Allen, Doisy, and J O Ralls, on whose experiments and methods of standardisation our work has been based

At first follicular fluid was used in manufacture, for while at that time we succeeded often enough in preparing the hormone from placenta in water-soluble form, this was by no means regularly the case The explanation lies in the fact that the hormone forms a true, non-colloidal solution (as we proved by its power to pass a dialyzing membrane), but at the same time is soluble in fats and volatile fat-solvents[2] The latter when dissolving fats take up the hormone too, and the larger the amount of fatty impurities present, the more difficult it proves to force the hormone to pass into the water For this reason it is best from the outset to extract the hormone with the least possible amount of accompanying fat This is the reason why we do not use alcohol for the extraction of the crude material, as the American investigators did, it dissolves too large an amount of impurities, and we discarded it at an early stage

---

[1] The authors cite only our German publications and these incompletely, but our method of preparation was published in English in the Proceedings of the Royal Academy of Sciences, Amsterdam, 1925, xxviii, No 10

[2] This probably is not true for the *pure* hormone its solubility in fat solvents is not a real one, but is simulated by the fatty impurities that always accompany it It may be mentioned here that B Zondek was the first who suggested the possibility of freeing the hormone from lipoids, and made experiments in this direction

Method of Placental Extraction.

From an experience of hundreds of experiments during the last two years we have found the best procedure to be briefly as follows:—

1 The placenta is used as fresh as possible

2 It is finely minced

3 It is boiled with one and a half times its volume of benzene for at most one hour

4. The benzene is filtered off as quickly as possible and on evaporating the fluid a yellow residue remains, weighing between 200 and 300 mg per kg placenta. It contains about 1000 mouse units (M U) This is only about one-third of the total amount present in human placenta[3] On treating it with water, sometimes part of the hormone dissolves to a clear solution but this is by no means regularly the case and often the fluid is turbid. It is therefore better to proceed as follows:—

5 The residue is repeatedly triturated with small amounts of 80 per cent. alcohol (usually altogether about 50 c.cm.) until the alcoholic layer after centrifugalising is quite colourless Thus a large part of the impurities are left behind

6 The alcohol is evaporated, the weight of the remaining residue is about half that of the first crude product.

7. The residue is shaken with 500 c cm of water and 1 5 to 2 c cm. of 25 per cent HCl for about half an hour

8 It is then left at a temperature of −2° C for about 12 hours

9 Then it is centrifugalised or filtered through glass wool.

10 Finally if the fluid is not yet quite clear it is filtered through asbestos (long fibres, treated with decinormal HCl and washed with water) Common filter paper should be avoided because it adsorbs[4] large quantities of active material

The solution thus prepared contains as a rule about 300–400 M U. The output may be increased to about 600 M U by extracting glass wool and asbestos with benzene evaporating the solvent and dissolving the residue in water in the manner just described.

Technical Modifications

This is not the place to discuss in detail all the modifications of technique or to explain why these were chosen Mention should however, be made of the fact that it is also possible to dissolve at least part of the residue from the benzene into water by simply conducting a current of gas (nitrogen, hydrogen carbon dioxide or steam) into it Air or oxygen should be avoided as the hormone is spoilt by oxidation All other additions, except HCl in the amount given proved unfavourable: organic acids—e g, acetic—are unsuited, as they often cause formation of emulsions that are very difficult or even impossible to break

Instead of using 80 per cent. alcohol to reduce the amount of solids of the first residue, in many cases use may be made of acetone We further tried several saponification methods, following the example of Allen, Doisy, and others A 2 per cent solution of Na_2CO_3 in water proved most useful, though we were able to show that the hormone can stand boiling with strong alkalies and acids even under high pressures and temperatures of 170° C, with water at 240°, in oil at 340°[5] We made use of this property to stand high pressures and temperatures without damage, to mince the placenta in an ideal manner, when heated with water in an autoclave it dissolves completely, after which the fluid may be treated in the usual way

Another method of reducing the dry residue is by making use of adsorption, which may, as has been said, cause so much trouble The solution of the hormone in 80 per cent alcohol is shaken with a special quality of activated charcoal, the hormone, together with a good deal of impurities, attaches itself to the charcoal and from this adsorption the hormone alone is freed by addition of phenol. On distilling off the phenol with the aid of steam a watery solution of the hormone is obtained[6]

The crude product prepared from placenta in the manner described weighs 0 1 to 0 2 mg. per M U. Many thousands of units have already been manufactured in this way in watery solution. Yet we are convinced that the output which at present only represents a fraction of the total amount present in placenta, may be considerably increased; and this may be accomplished by reduction of the dry residue of the first extract, which contains large amounts of impurities

In our first communication we showed that the dry residue per M U may be less than 0 1 to 0 2 mg, and we proposed the name Menformon for that water-soluble hormone which in at most 0 1 mg contains one mouse unit The water solution of hormone from placenta always easily reached this standard and even far surpassed it, so that we could reach a limit of 0 0008 mg per mouse unit—i e, about 0 003 mg per rat unit This was accomplished for instance by again shaking out the watery solutions with benzene; on evaporating the benzene the residue is immediately dissolved in water, or one of the described processes of purification is applied once more. Dialysis may also be made use of if a certain degree of purity has already been reached· then only a small fraction of the hormone is adsorbed by the membrane[7]: with more impure solutions the losses are too big in dialysing

We found that at last the hormone, purified as far as possible with our present methods is no more soluble in the common volatile fat-solvents but only in water (see above) so that its lipoid nature becomes very doubtful

Properties of the Hormone.

So far we have refrained from saying anything about the physical or chemical properties of Menformon We must express some doubt about the value of certain statements in the literature—e g, that the hormone should contain a considerable amount of sulphur (Dickens), or shows a positive histidine test (Dickens, Zondek)—about the accurate chemical analysis by Hartmann[8] from the Ciba Laboratories and even the descriptions of Ralls, Jordan, and Doisy[9]) All these authors worked with materials which consisted only to a very small part of the real hormone The recent investigations of Dickens, Dodds, and Brinkworth, for instance, were carried out upon a material of which 0 5 mg represented 1 rat unit, considering the degree of purity reached by us less than 0 005 of their material must have been the real hormone Our own preparations, some of them not fully purified did not show any certain sulphur content and did not give a histidine test

With regard to the biological properties of Menformon it is possible to say more Apart from its power of causing typical œstral changes in castrated rodents, and even of keeping the animals for six weeks in this state continually by daily injections, we can mention the following facts Menformon is able to induce œstral changes in juvenile and in senile animals[10] It promotes growth of the female genitalia (uterus and vagina) Recent experiments have shown[11] that the lowest limit for obtaining with certainty acceleration of growth of these organs in young rats is 0 00004 mg of Menformon pro die (injected on five successive days) in rabbits we obtained certain growth with 0·0008 mg (also on five successive days)

Further, Menformon shows a typical antimasculine effect, it inhibits the growth of testicles, penis &c, of young males Moreover, it has a specific action upon the secretory parts of the mamma[12] in female as well] as in male individuals, but seems to have no influence upon the nipple or mammary fat Finally it acts specially upon metabolism, but only in *castrated females, not in castrated males* [10]

---

[3] Provisional standardisations are carried out with several dilutions of the same batch each dilution being injected into at least three castrated female mice For the definitive standardisation we always use 12 mice

Extracts prepared in quite similar manner from liver and other organs did not show any sign, or at most faint traces, of the various actions of Menformon mentioned above, even if the dose was increased a hundredfold Thus we think we are justified in regarding these results as typical for this female sexual hormone Mention may be made of the fact that we have been able to prepare from testes substances, also soluble in water, that are capable of inducing œstral changes The output was about equal to that from ovaries from which the follicular fluid had been removed [13]

The practical clinical results are as yet not numerous enough to draw definite conclusions, but several cases are already known in which after amenorrhœa of long duration menstruation was induced by doses of 30 to 80 mouse units

We thought it justifiable to make such experiments and even to make the preparation available for practical use on a larger scale, as we are convinced, from experiments upon animals and upon ourselves, that *it is quite harmless* But this has only been possible on account of the stress laid from the outset upon the highest degree of purity (0 1 mg pro M U as a maximum) For such preparations do not have the least influence upon heart, respiration, or blood pressure, even when injected intravenously, whereas less pure preparations, such as have been described in England by Dickens and Dodds [14] towards the end of 1925, exert an appreciable lowering action upon blood pressure We think those authors are not quite justified in ascribing this to the hormone itself, it is more probably an effect of the impurities

EXOGENIC DERMATITIS *

BY W J O'DONOVAN, M D, M R C P LOND,
PHYSICIAN IN CHARGE SKIN DEPARTMENT, LONDON HOSPITAL

THE term "exogenic dermatitis" may be conveniently used to cover dermatitis due to any sort of external irritant The result of the application, over a long or short period of time, of external irritants to the skin is the appearance in the sufferer of dermatitis varying in all degrees, from a subjective discomfort without physical signs, through stages of redness that may be discrete and papular, purulent, or scaling, the formation of abnormal pigmentation, warts, up to even the development of ulcers or malignant carcinoma cutis

The classification of occupational dermatitis, or more widely of dermatitis due to external irritants, is a thankless and unsatisfactory task It has been attempted by Prosser White [1] but considering that the factors of cause, of time, of constitutional diathesis, and of chemical irritants all enter into the consideration of any one case, such an attempt, if at all accurate or exhaustive, can only be for the mental satisfaction of the writer, and it would be better for the development of this branch of dermatology that attention be given to elucidating the many factors of skin irritants present in civilised life rather than attempts be made to draw confines about an expanding subject

Predisposing Skin Types

There are two common types of abnormal skins, both of which are liable, to a greater extent than is usual, to give way rapidly before external irritants, first, the dry or xerodermatous skin, secondly, the skin that is abnormally moist from sweating In the ichthyotic skin there is an absence of natural grease which protects it, when exposed continuously to water, against maceration and against the effect of weak acids and alkalies This dry skin cracks easily *in east winds, such cracks become open sores in the* presence of irritating chemical dust, but it is among the abnormally moist patients, in the first instance those who work in dusty occupations, particularly cement dust, that the resistance of the skin is lowered by the formation of a poultice of moistened humus retained in the flexures of the hands, the feet, or behind the ears

There is a constitutional skin affection known as *cheiropompholyx* which brings a great element of difficulty into the diagnosis and proper adjudication of occupational skin affections This "disease" is characterised by an outcrop, often seasonal, of irritating minute blisters between the digits or on the palms themselves These blisters rupture leaving raw open sores, which scale and may become septic A skin that suffers from this condition is very sensitive to many external irritants, whether it be wind, sunlight, soap, water, formalin, or acids Such cases are readily healed, but may relapse also readily. To what extent a present cutaneous disability may be due to an occupationally started outcrop of cheiropompholyx months or years previously is a problem in every case difficult of solution A domestic cause acting recently may have been as potent of mischief as a trade irritant of an earlier date A constitutionally livid condition of the extremities may be responsible for a most engaging problem, as in the case of E D, aged 15, a van boy, who came to see me in the winter of 1924 with severely ulcerated chilblains of his hands We could hardly question that were he unemployed, and with his hands continually in his pockets, he would not be suffering from ulcerated chilblains, but, as he worked in winter daily, with uncovered hands that grasped the van rope, we have to concede an ætiological factor in his employment The lesson to be drawn is that an employer who persists in sending out into the streets a boy with purple hands is inviting a claim for occupational dermatitis that would be very difficult to rebut

Domestic Irritants.

It is scarcely realised to what extent the modern home is, in fact, a small chemical factory It would be as well for a practitioner to run through the pages of a catalogue of a stores or of an Italian warehouse to bring to mind how many are the noxious agents that may come in contact with a normal or unduly sensitive skin of a person within the—ordinarily considered sheltered—domestic atmosphere. A housewife has her hands immersed in water for several hours a day, so that the *water maceration dermatitis* which is often seen in barmaids and hospital scrubbers may be seen too in the hands of the housewife herself Dermatitis due to alkalies is a common occurrence due to the use of soda and soda preparations, to strong soaps, to chloride of lime for bleaching purposes after washing, and, as in the case of one patient, L H, to the manufacture of her own soap learnt in the back woods of Canada

Diluted acids are used for the cleansing of lavatory basins and lavatory pans. The composition of furniture polishes, leather preservatives, and metal polishes is unknown to me, nevertheless, these are most certainly deleterious to the skin Quick drying enamels and paints, special rapid paint cleansers, storage batteries, disinfectants, and insecticides are all in perpetual household use, and any or all may explain an obscure dermatitis occurring in a woman of the lower or middle classes

Pattern Reaction

It is important to appreciate that the same cause operating on many skins may produce different results, varying either in kind or in degree Some bakers in every attack show a follicular purulent dermatitis, others never progress beyond an erythematous and scaling state of the hands and forearms Some cases of lime dermatitis recur rapidly on the arms and neck, in others the dermatitis becomes rapidly distributed *to all the flexures*, in a rarer group of cases a neglected attack will always be followed by a universal erythema

[14] Biochemical Journal, 1925, xix No 5

* Lecture delivered to the Hull Medical Society, March 4th, 1927

If the patient is a psoriatic by nature, then his reaction to an external irritant will be psoriasis in type A youth, aged 18, was transferred from outdoor labouring to dyeing in an East-end factory, and after a week had to give up his work from an acute but typical confluent psoriasis extending from his wrists to his elbows It is fair to state that two factors were at work in this case; his forearms were continually immersed in aniline dye, and he cleaned them twice daily with a solution of lime, but neither aniline nor alkali usually have a psoriatic reaction In this case there was a pattern reaction in the common site of dermatitis due to occupational irritants

Some skins ulcerate with extreme ease, and in such, where the patient works in cement, in chrome, in arsenic, or in fulminate of mercury, the rapid production of ulcers upon the fingers or eminences of the face is the pattern reaction of this constitutional type or diathesis In the trade such ulcers may be recognised as "chrome holes," or as "cement burns,"[2] or "powder holes," but these are not the common reactions to any of these irritants They are specific to the patient so affected They may be associated with and surrounded by, a red scaling condition of the skin due to the same cause, or such ordinary dermatitis may not develop at all H S developed these acute ulcers on his fingers ten days after his employment as a painted glass-maker; arsenic and cobalt were the two particular chemicals he handled. A special name, beautifully descriptive of some of these circular ulcers, with acute central sloughs, is "pigeonneau" in use by the French

Ætiological Difficulties

That industrial complexity has developed at a greater rate than the educational development of the workers is a factor that has long hindered the development of our appreciation of the full importance of the effect of external irritants on the skin As a rule our labourers are ignorant of the natural composition or destination of the materials they handle It may be that active curiosity is discouraged by their employers; it may be that many trade processes are necessarily kept secret from trade competitors, yet it is singular that a worker will handle a substance for 20 years and be satisfied to call it "red acid" and know no more about the stuff he has transported so continuously from barge to wharf

Another factor of difficulty is that the trade label of the worker may be most misleading as to the hazardous nature of his employment A boy was admitted under my care in St James's Hospital for a second attack of acute purulent dermatitis of his hands and feet He gave his occupation as that of "tea boy," and at first he was considered a case of dermatitis due to want of natural cleanliness, but on his second admission, when pressed he explained that his work was to carry continuously tins of freshly made tea throughout the day to the hundreds of workers employed in putting up a large new building in the City of London Cement dust and lime lay thickly about the scaffolds, ground, and stores He shook this alkali dust out of his shoes every night and the proper classification of his affection was an alkali dermatitis, an ætiology concealed by the designation of "tea boy"

I have elsewhere published at length my difficulty in unravelling an outbreak of dermatitis among miners which turned out to be alkali or lime dermatitis among underground compressed air tunnellers who burrowed in the London clay A baker may show red forearms due to the desiccating action of flour aggravated by the avulsive effect of dough upon the many hair follicles of his forearms Another baker's "itch" may appear as a follicular purulent *dermatitis*, while a third baker may show carcinoma cutis of the thumb due to the daily friction of a heated iron pole with which he regulates the oven fires[3] Under one occupation there may thus be three distinct hazards The patient may be most disinclined to help in a decision from a desire to carry on at work; particularly is this the case among countrymen Patients coming at different seasons of the year with a second, third fourth or even fifth attack of erythematous or bullous dermatitis of the hands and face due to hops, tomatoes, to chrysanthemums, or to lilies, may offer no explanation because a recognition of what they intuitively know is displeasing to them The different seasons at which various plants are handled in quantity is part of the everyday knowledge of the dermatologist

Factors making for Chronicity

It is reasonable to expect that, with the removal of the patient from the exciting cause, the cure of the skin condition will be rapid and satisfactory Ordinarily this is so, difficulty arises when there is a constitutional instability of the skin upon which the occupational or external factor has been added. This factor must be worked out with extreme care, as such cases often come before the judiciary under the Workmen's Compensation Act The underlying factors I would stress at present are chronic urticaria cheiropompholyx congenital ichthyosis and a neuropathic taint

J M suffered, and was treated and apparently cured of an alkali dermatitis due to cement Later he was brought to see me by the insurance company's doctor now suffering from a widespread urticarial eruption, starting on his back He had not resumed work after discharge from hospital treatment The rash became well-scratched into a condition of moist and scaling dermatitis of the extremities, and this was held by a medical referee to be, against my opinion a case of *relapsed occupational dermatitis*

M B suffered from an admitted attack of sugar dermatitis She completely recovered, and while away from work suffered from an acute outbreak of cheiropompholyx on the fingers This case, fortunately came before the same referee while the skin was apparently well Subsequently she was seen with an acute attack of cheiropompholyx, which she afterwards rapidly scratched into a condition of moist erythematous dermatitis of the forearms and hands From this she recovered, but was later admitted to an infirmary with a carbuncle of the lip, from this she died

When did the "causa causans" cease to act? Patients with congenital ichthyosis may suffer from intertrigo of the flexures winter after winter[4] or sometimes only in brilliant summers Such patients exposed to lime dust or to pitch dust may have these attacks aggravated, but the assessments of responsibility assigned to the different causative factors are always speculative

The nervous element has to be most carefully considered in a case of any duration for in the case of the neurotic patient—a type well recognised by the general physician—itching and scratching rapidly become an ingrained mental habit Dull and unattractive patients suffering from occupational dermatitis find themselves for the first time in their lives free from the toils of daily work in receipt of money and the subjects of compassionate interest of doctors nurses solicitors county court judges, relatives, and friends This limelight and drama are naturally intoxicating and attractive, and unconsciously the patient's attention is focused on their skin in a way we are familiar with in cases of hypochondriacism, of floating kidney, and mucous colitis

As irritable hearts excused men from the battlefield so an irritable skin excuses patients from the hazards and unpleasantness of industrial life and on this account all long-continued cases of dermatitis should have their palatal and tendon reflexes tested the presence of tremor and anæsthesia to pinprick noted, and the effect of sedative treatment tried The healing effect of impressive X ray treatment is excellent, but is far out of proportion to the therapy actually applied to the skin while the effect of a satisfactory financial settlement to these cases is immediate and gratifying

When did the "causa causans" cease to act? Patients with congenital ichthyosis may suffer from intertrigo of the flexures winter after winter,[4] or sometimes only in brilliant summers Such patients exposed to lime dust or to pitch dust may have these attacks aggravated, but the assessments of responsibility assigned to the different causative factors are always speculative

The nervous element has to be most carefully considered in a case of any duration for in the case of the neurotic patient—a type well recognised by the general physician—itching and scratching rapidly become an ingrained mental habit Dull and unattractive patients suffering from occupational dermatitis find themselves for the first time in their lives free from the toils of daily work in receipt of money and the subjects of compassionate interest of doctors nurses, solicitors county court judges, relatives, and friends This limelight and drama are naturally intoxicating and attractive, and unconsciously the patient's attention is focused on their skin in a way we are familiar with in cases of hypochondriacism of floating kidney, and mucous colitis

As irritable hearts excused men from the battlefield, so an irritable skin excuses patients from the hazards and unpleasantness of industrial life and on this account all long-continued cases of dermatitis should have their palatal and tendon reflexes tested the presence of tremor and anæsthesia to pinprick noted, and the effect of sedative treatment tried The healing effect of impressive X ray treatment is excellent, but is far out of proportion to the therapy actually applied to the skin while the effect of a satisfactory financial settlement to these cases is immediate and gratifying

Clinical and Laboratory Notes.

A CASE OF ACUTE ANAPHYLAXIS

By Leonard S Dudgeon, C M G, C B E, F R C P Lond,

PROFESSOR OF PATHOLOGY, UNIVERSITY OF LONDON

The details of the case about to be described are of such interest that I have decided to place them on record

The Case Related

A lady, a keen horsewoman, had suffered from horse fever and severe horse asthma since childhood On Dec 2nd 1926, I gave her by the intradermal method 0 1 c cm of normal horse serum Within three minutes of the injection a local blister developed followed by redness of the skin over a wide area of the arm in the vicinity of the serum injection, but no further inconvenience occurred She was not hypersensitive to any foods or pollens It was considered advisable to attempt desensitisation

On April 29th, 1927, nearly five months after the dermal injection of 1 drop of horse serum, I gave her at 5 P M 0 25 c cm of normal horse serum subcutaneously, and as far as I know the inoculation was entirely subcutaneous Almost immediately after the injection *blood-stained serum* escaped from the wound puncture, and within two minutes she felt faint and the pulse was rapid Within five minutes of the inoculation of the serum her condition was as follows There was œdema of the eyelids and very considerable œdema of the lips and face She was completely comatose with partially contracted pupils A continuous stream of clear, white frothy exudate was escaping from the mouth The breathing was rapid and stertorous, and the pulse could not be felt at the wrist, but a fluttering was perceptible over the cardiac area I gave her artificial respiration for 1 hour and 20 minutes, because if it was stopped for more than a few moments the cyanosis rapidly increased An injection of 1 in 10,000 adrenalin chloride (1 c cm) was given subcutaneously During the period required for filling the syringe and giving the injection her husband, who was alone with me during the whole of the most critical period of the attack, continued the artificial respiration

Very gradually the cyanosis lessened, the output of fluid from the lungs diminished, and the pulse became obvious at the wrist At the end of the time that artificial respiration was employed consciousness had returned and the pulse had considerably improved She then had a violent attack of vomiting which lasted off and on for about 20 minutes, followed by a feeling of intense cold which was partially relieved by warm applications to the body Hot drinks could not be taken because of the feeling of intense nausea which followed the violent attack of vomiting She was then removed to her own house in an ambulance, and cardiac stimulants were administered Inhalations of oxygen were given at frequent intervals for many hours, as it was found that they considerably relieved the cyanosis and respiratory distress

Within one hour of the injection of horse serum a diffuse mottled eruption spread all over the body, the colour of the rash fluctuating with the degree of cyanosis The rash persisted for about 12 hours and then gradually faded For seven hours after the inoculation her temperature, taken in the mouth and axilla, would not register above 95° F At 2 A M the temperature was 99 6° F , at 6 A M 100 4° F , from 10 A M to 2 P M 100° F , from 6 to 10 P M. 99 4° F , and then it fell to normal, at which it has remained ever since except on one occasion

Considerable abdominal distension occurred about midnight (about seven hours from the onset of the attack), it was relieved by means of 1 c cm of pituitrin subcutaneously and 2 oz of glycerine per rectum. The pulse-rate, which had remained during the night about 110 to 120, at 4 A M increased to 130 and 140 per minute together with considerable increase in the respiration-rate She was then given ¼ gr of morphia and 1 c cm of 1 in 10,000 adrenalin chloride From this point onwards a general improvement in her condition occurred which was maintained, and by 7 A M , or 14 hours from the time of the serum inoculation, the cyanosis was only just apparent, respirations were 30 to the minute, and the pulse rate was 100 The rash disappeared very gradually, although it had a tendency to reappear at the site of the injection of the serum in the arm for the next 24 hours Her general condition rapidly improved, and 48 hours from the onset she was suffering only from mental fatigue and bodily weakness

Five days after the injection of the serum the patient developed pain and considerable œdema of the arm spreading from the site of the inoculation, and accompanied by a mottled red rash confined to the same area, tenderness of the axillary glands, and a temperature of 99° F The local reaction was treated with complete rest for the arm and local applications of evaporating lead lotion In 48 hours the only evidence of this local reaction was slight tenderness at the site of the inoculation There have been no further local or general reactions, and three weeks from the onset of the attack she is none the worse for her very severe illness

Commentary

In my experience of acute anaphylaxis this case presents several features of great interest and importance

The fulminating onset was produced by the subcutaneous injection of 0 25 c cm of normal horse serum into an individual hypersensitive to "horse," who had received one previous injection of 0 1 c cm. of horse serum directly into the skin five months previously No subcutaneous, intramuscular, or intravenous injection of horse serum had been given on any previous occasion, and no other foreign protein had been administered The appearance of definitely blood-stained serum escaping from the needle puncture almost immediately after the injection of four drops of horse serum is a feature I have not heard referred to by any previous worker, and I have not seen it myself The blood-stained serum actually oozed from the wound puncture

The almost immediate onset of subcutaneous œdema, severe pulmonary œdema, extreme cyanosis, heart failure, and coma appeared to me to justify the conclusion that the patient's condition was hopeless within five minutes of the injection of 0 25 c cm of horse serum The patient's husband, who served all through the war, told me later that his wife's appearance brought back to his memory the first attack of mustard gas with which he had had a very full acquaintance I personally believe that artificial respiration saved her life The sections of lung which I have examined from cases of acute anaphylaxis in the human subject have shown a very diffuse œdema as the characteristic lesion This patient suffered from a very profuse watery discharge from her mouth for over an hour—in fact, she was being drowned in her own body fluids If it is ever my misfortune to have to treat a similar case on a future occasion I shall certainly employ artificial respiration, in spite of the fact that it is the most severe exercise with which I am acquainted

The last point of interest to which I must refer is that the patient has very little knowledge of her illness during the whole of the very acute period which lasted about 14 hours

In conclusion, my greatest thanks are due to Dr. L W Shelley, whose advice and help during the whole night when the patient was so seriously ill were of the utmost value

A NOTE ON THE
SPLEEN AND IMMUNITY

By William Susman, M D , C M Q U Ontario.

An investigation of amyloidosis which I have undertaken has suggested (1) that the spleen plays an essential rôle, and that splenic pulsations are a significant factor in the condition, and (2) that there is a similarity in the distribution of lesions in and about the Malpighian bodies in amyloid disease and in acute infections

As amyloid disease is usually due to a prolonged bacterial infection accompanied by suppuration, the probable connecting link between amyloidosis and acute infections is immunity If so, what is the splenic share in immunity, and what changes result from alterations in the rate and intensity of splenic pulsations ?

On the one hand, many workers, including L. Aschoff,[1] have shown that the spleen and the reticulo-endothelial system in general participate in the production of immunity Sharpey-Schafer and Moore [2] however have demonstrated that atropine will diminish and aqueous brain extract will augment, the rate and intensity of splenic pulsations With these observations before us we can investigate the effect of alterations in splenic pulsations on the production of immunity

---

[1] Ergebn d inn Med u Kind , 1924, Bd xxvi

Experiment I

Twelve adult rabbits were immunised against *Bacillus typhosus* Four of them were used as controls, four others received accompanying injections of atropine, while the remaining four were inoculated at the same time with aqueous brain extract

The results may be summarised as follows (1) Serum of an animal injected with brain extract alone gave negative results. (2) Atropine injections lowered the agglutination titre (3) Brain extract in six days gave 4 times, in 11 days 23 5 times, and in 16 days 32 times the average titre obtained in the controls.

Experiment II

Adult mice were injected with pneumococcal broth sufficiently diluted to kill the controls in about four to six days One hundred animals were used as controls; a further 116 were also injected with brain extract. The animals treated with brain extract lived on an average about three times as long as the controls Approximately 40 per cent of them outlived all the controls, and 17 per cent to 25 per cent lived over four weeks

A further group of 20 was divided into five sections All received a pneumococcal injection while sections of the five were also injected with either glucose peptone cream or brain extract All animals in the four control sections—i e those which received pneumococcal broth, broth and glucose, broth and peptone, and broth and cream—gave similar results, whereas all in the pneumococcal broth and brain extract section were alive on the fifty-seventh day

Conclusions

1 Brain extract induces an increased immunity reaction, as indicated (*a*) in mice actively infected with virulent pneumococci (*b*) in the increased agglutination titre in rabbits immunised against *B typhosus.* 2 It does not act on a protein-shock basis 3 That the spleen is influenced is at present hypothetical

This investigation was carried out under a grant from the Government Grant Committee of the Royal Society I am also indebted to Prof Shaw Dunn for supplementing the available supply of experimental animals

Medical Societies.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE

A MEETING of this Society was held on May 19th in the rooms of the Medical Society of London Dr ANDREW BALFOUR the President in the chair

Dr A T STANTON (Chief Medical Adviser to the Colonial Office) opened a discussion on the

Organisation of Medical Research in the Tropics

and laid before the meeting a scheme of representation One of the general criticisms which had been directed against such a scheme was he said, that it was bureaucratic This might be taken to mean that governments should not concern themselves with research a view with which he had no sympathy: indeed he considered that the encouragement of research was one of the principal functions of a government, seeing that it was concerned with the maintenance of a high standard of health among the people He would place the research under a medical department and that again was a subject of controversy some contending that it should be conducted outside the medical department which ought to concern itself only with such subjects as sanitation and the treatment of disease In the British tropical colonies there were 60 to 70 officers who could be designated medical research workers, chiefly distributed over the East and West African colonies, Ceylon the West Indies, and the Western Pacific areas If by research was meant any work intended to add to knowledge of the causation prevention and treatment of disease, then all tropical medical workers were research workers Medical graduates who went to the tropics were of an inquiring mind, and whatever the particular sphere of activity they went to fill, research in the proper sense of the word might be undertaken by them

An important point which was frequently discussed, said Dr Stanton, was as to whether medical research of a tropical order ought to be done in the tropics, or whether it could be better carried out in this country Having spent most of his medical life in the tropics, he had a leaning towards the former view, though he agreed that certain lines of research might be more effectively pursued in this country One of the disadvantages in the past, as most tropical investigators had found, was their lack of contact with those doing similar work in this country though no tropical worker had appealed in vain to the British Museum authorities on such subjects as entomology Latterly the Medical Research Council in England had been anxious to extend its activities to the tropics This seemed to be a good time therefore, for establishing a liaison between tropical organisations and research agencies in this country, and the nucleus of the scheme which he submitted was the formation of a joint committee of the Colonial Office and the Medical Research Council to receive the name the "Colonial Medical Research Committee." The endeavour would be to establish contacts, through this committee, with all the organisations in this country concerning themselves with medical research problems of the tropics and perhaps with those in other countries. and with international organisations, such as the League of Nations. the International Health Board, and the Rockefeller Foundation Cooperating in this work there should be such bodies as the Royal Society, the schools and societies of tropical medicine, the research institutes the Lister Institute, the Committee of Civil Research the Bureau of Hygiene and Tropical Diseases, and the Imperial Bureau of Entomology

A very important question went on Dr Stanton. was how to disseminate information and reports on research work and in this connexion there was already in existence a bureau of tropical diseases which had well carried out its function His suggested committee would act through a medical secretariat working on a whole-time basis, who would maintain the needed contacts and generally attend to the question of tropical diseases Dr Stanton said he fully realised that the mere provision of machinery did not necessarily mean anything, that the personnel was the great requirement, but, given a personnel of the necessary quality and calibre, it was all the better to have an efficient organisation

Discussion

Prof WARRINGTON YORKE (Liverpool School of Tropical Medicine) said that the first question to be asked was whether the present state of affairs was or was not satisfactory. If it was not. what was wrong? To judge by the size and number of papers which were contributed on tropical subjects, the state of affairs might be considered actively favourable, but the opinion he had derived from reading and summarising these papers for publication was that far too much was published He was inclined to say that more work and less printing would be a good thing He would not discourage workers but would ask that their investigation should be more careful, thoughtful and critical, and that observations committed to paper should be written in full cognisance of what had been done before Research done without due care and without proper controls not only wasted the time of the reader, but might very well be mis-

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

A MEETING of this Section was held on May 20th, Prof A. DONALD, the President, in the chair Mr. A. S PARKES read a paper on the

Internal Secretions of the Ovary.

The active life of the uterus he said, *might be* regarded as a series of preparations for the fertilised ovum. the follicular phase, associated with maturation and rupture of the follicles, was followed by the luteal phase, associated with *development of the* corpus luteum In the rat the preparation made for the ovum was very slight. but *in the dog and rabbit* the luteal phase was so marked that it produced a pseudo-pregnancy—involving accessory organs like the breast—when fertilisation was absent When involution of the corpus luteum ended the *pseudo-pregnancy*, *there might* be phenomena characteristic of true *parturition—e g., lactation and nest-making.* In woman, probably, the luteal phase dominated the cycle menstruation being a uterine degeneration after pseudo-pregnancy Ovulation was supposed to occur 13–15 days after the onset of the previous menstruation. Development of the *corpus* luteum then induced development of the uterus, and its involution after about ten days caused the retrogressive changes producing the menstrual flow, which might be described as the abortion of unwanted decidua Experiment proved the ovary *to be essential for the early development of the* accessory organs, for their cyclic activity in the absence of pregnancy, and for maintaining pregnancy and mammary development Its control was probably hormonic as transplantation would prevent the bad results of oöphorectomy

Œstrus-producing *qualities in any* substance could now be detected easily by examining vaginal smears The first definite œstrus-producing extract was obtained by Allen and Doisy (1922) from liquor folliculi. and this gave rise to the theory that maturation of the follicle was the direct cause of œstral changes *But the hormone had been found in* ovarian stroma, in fluid from hollow corpora lutea, and in placenta, and the œstral cycle *persisted after* obliteration of the follicles by X rays The functions of the corpus luteum hormone were *sensitisation of the* uterus after ovulation, maintenance of pregnancy, inhibition of the œstrus during *pregnancy. and* development of the mammary glands; but extracts of corpus luteum had been far less successful *than* œstrus-producing extracts, and so far had performed only one function of the intact *corpus—namely*, inhibition of œstrus

There were thus available an œstrus-inhibiting and—in very impure state—an œstrus-producing hormone (*œstrin*) Injection of œstrin during the luteal phase of the *infertile cycle or during* pregnancy or lactation, might override the domination of the corpus luteum bringing animals into œstrus and terminating pregnancy The converse might also work. Œstrin was *probably* responsible for maturation of the Graafian follicles It was also highly probable that *injection of œstrin* might remedy conditions due to low ovarian activity; whilst the hormone of corpus luteum would be useful in those cases of amenorrhœa premature birth or mammary deficiency in which *the corpus luteum* was at fault. More work must be done, however, before this extract could be clinically available Œstrin had been used for amenorrhœa sterility. and delayed parturition Marshall and Dixon s work suggested that parturition was caused by excitation of the pituitary due to the ovarian activity following retrogression of the corpus luteum It was doubtful if œstrin would be of value for cases of infantile uterus The sudden hypertrophy *it caused* in the infantile uterus of the immature rodent was due to an effort to come into œstrus, and seemed to be purely temporary

The PRESIDENT remarked that in menopausal cases he had never seen any benefit from the use of ovarian extract

Prof. BLAIR BELL pointed out that the corpus luteum persisted in the *psychological pseudo-*pregnancy of girls who had "gone wrong" and missed two or three periods from fright It should be called the "corpus luteum of pseudo-pregnancy." After the trial of a recent case of alleged criminal abortion, he *had examined* sections of the uterus of the woman who died, and it was obvious that she had never been *pregnant at all*, and that the corpus luteum *found in* her ovary was the persistent corpus luteum of pseudo-pregnancy. In experimental animals the follicular elements all lay on the surface and could be removed, *leaving only the interstitial cells*; left alone, these *could keep* the uterus active and maintain sexual *appetite and œstrus Observations* must not be confined to the pelvis; intense destructive atrophy of the ovary and uterus followed clamping of the pituitary stalk.

Mr. A W BOURNE had tried œstrin in three cases *for the induction* of labour without result One patient *had had a show and some pains after 20 rat-units*, but it passed off, and a second injection had no result. The injections were very painful, and in his opinion the dosage was inadequate He mentioned a case of *sterility in which* injection had produced all the symptoms of menstruation, together with a very copious clear mucous discharge, but no bleeding

Mr. PARKES, in reply, pointed out that an active ovarian extract had only been available for three years. Recent work on extraction of œstrin in a water-soluble medium might obviate the pain of injection. In late pregnancy large doses were required to *produce abortion, since the active corpus* luteum had to be overridden

Mr. LEONARD PHILLIPS reported a case of

Spontaneous Separation of the Cervix in Labour.

The patient was a primigravida aged 44 in whom a breech presentation had been turned in the antenatal *department* Labour was induced by bougies at the thirty-seventh week because *the head* did not engage readily. After six hours of good pains *the* cervix *had* dilated sufficiently to admit two fingers but was rigid. Twenty-one hours later there had been no further dilatation, although chloral, bromide *morphia, and* scopolamine had been freely given After 36 hours the general condition was good and *the head almost on* the perineum, an œdematous lip of cervix was palpable behind it The os still admitted just two fingers Two hours later forceps were *applied on* account of fœtal distress, but as soon as the hand entered the vagina—before the forceps blade was passed—a ring of cervix slid out of *the vagina* The child was easily extracted and did well The puerperium began quietly but *after* four hours abdominal distension developed, *the pulse* was *140*, and the temperature was 100° F On examination no rupture was found *a raw area on the* anterior vaginal wall was cauterised and painted with 1 per cent violet green while the vagina was plugged with gauze soaked in *1/500 flavine A blood* culture showed pure growth *of Bacillus coli* The patient died four days after delivery.

It appeared subsequently, said Mr. Phillips that the œdematous "*posterior lip*" was really the anterior lip of a cervix already separated and imprisoned between the fœtal head and the *sacrum*. In this case patience in the presence of a slowly dilating cervix had had a disastrous result The limitations of *antenatal* care were illustrated The lessons were· the necessity. under scopolamine-morphine narcosis of frequent vaginal examinations. and the importance of considering Cæsarean section in cases of slow dilatation in elderly primiparæ A post-mortem was *refused, but it* was clear that there was no rupture of the uterus and no *peritonitis* merely a septicæmia from infection of the laceration

Dr J. P HEDLEY *said* that so rare a case as this did *not* justify alteration of the rule that vaginal examinations *should be as few* as possible

Mr EARDLEY HOLLAND mentioned cases of evulsion of the cervix from application of forceps, or pressure in cases of contracted pelvis, and spoke of the utility of rectal examinations for finding the state leading, it certainly did not advance knowledge Often when a man had been working at a particular subject and then took a period of leave after sending his contribution, no more was heard of the subject after his return to duty

There were, said Prof Yorke, three types of people concerned in the investigation of medical science in the tropics (1) those sent out from time to time on special commissions, (2) the staffs of the various laboratories scattered through the tropical colonies, and (3) those whose prime duty was the diagnosis and treatment of disease, but who, with commendable enthusiasm, found time and opportunity to do some research The problem of the isolated worker was one of some difficulty It was difficult to assist a man who was working by himself, he had little literature, and small opportunity of knowing what others were doing Such a man, however, should certainly be encouraged, and the committee suggested by Dr Stanton would be a useful channel for providing help It was chiefly, however, from the laboratory worker that advance must be looked for, as only he had the special training and equipment needed Still, the laboratory often lacked the necessary material, and was cut off from intercourse with clinicians. He would not separate the research from the clinical sides, especially as the aggregation of workers together would counteract the danger of stagnation

The director of such a laboratory was the person who made for the success or otherwise of the establishment, and seniority of service might be of little value as a criterion of fitness for such posts In order to get the right men for this work it was necessary to make the conditions of service attractive, and certainly they should not labour under any financial disability Leave should be granted periodically so that men could study and keep themselves abreast of new knowledge, and the staff should be sufficient to ensure continuity in a piece of work while a member of the staff was on leave

Sir LEONARD ROGERS remarked that it was the function of editors of scientific journals to refuse articles which were below the necessary standard He went on to speak of the tropical research done under the Government of India India was fortunate in having what it was desired the tropical colonies should have Candidates for the Indian Medical Service had first to work for several years as probationers, and were thus required to prove their worth before being granted a position in the laboratory This created a class of men suitable to fill vacancies in laboratories anywhere Sir Leonard Rogers described how merchants in India were induced to provide money for research, having seen that this research meant less sickness among their employees In order that there could be advances, he said, it was of the utmost importance that there should be continuity of effort.

Prof R T LEIPER said that the scheme put forward by Dr Stanton was based on a colonial unit, and he saw no prospect under such a scheme of attaining the integration of research work throughout the tropics which some had been looking forward to for many years He favoured an imperial scientific service, with a medical side, especially as laboratories in the colonies were concerned with the routine work as well as research, and research would always be the Cinderella of the laboratory so long as it was under the direction of the medical services He would prefer to see research attached to the section of medical education, and investigators should have more freedom than was promised in the scheme now outlined At present there was no responsible body in the tropics to supervise this work He did not agree with Prof Yorke's remarks about the literary output of workers in tropical diseases, it was good for a man to commit his ideas and his findings to paper, for only thus would he distil down what he had been doing and become definite with an eye to possible criticism

Colonel F. HARVEY spoke of the organisation of research in the army At the War Office there were special directors of hygiene and pathology Sir William Leishman was the first to hold such office, and it was largely through his efforts that this organisation was instituted There were also deputy directors in all the army stations abroad The drawback was that the work concerned only the British soldier, the investigators were not brought into contact with the enormous material presented by the native races At the War Office there was, too, a pathology advisory committee on which the Medical Research Council and the Royal Society of Tropical Medicine and Hygiene were at present represented This committee kept in close touch with the medical staff in the tropics There was also a bureau in connexion with the army, and the men on the medical staffs were kept supplied with technical literature Where necessary, reports sent home were criticised and returned He agreed with Prof Leiper that publication of work should be encouraged as much as possible

Dr P H MANSON-BAHR did not agree that the results of work should be suppressed, opinions changed with time, and if it had not been for the desire to publish work which seemed to hold out promise, some momentous discoveries would not have been made when they were Moreover, it was the custom when making a new appointment to have regard to what a candidate had written, and, as an index of his activity and ability, this record could not well be ignored At present the worker in the laboratory was penalised financially in comparison with the man who was diagnosing and treating disease The personal factor must always be given a high place, no amount of official organisation could make up for defects in the man who actually did the work A combination of personal fitness and adequate training with sufficient equipment should be sought for this work Some official was needed who would travel round and see what everyone was doing He agreed that the laboratory doing routine work was not the place in which to conduct research

Dr DE LANGEN (Holland) deprecated the attempt to keep scientific research within recognised boundaries, it was always liable to take an unexpected turn He did not think English workers published too much, and they certainly had the faculty of apt and succinct expression He would like to see an international organisation established in connexion with medical research and a freer international scientific exchange

The Rev Mr CHESTERMAN pleaded that the profession should accept the help of missionary hospitals in the tropics, especially as missionaries could secure labour and inquiries at practically no expense He felt sure missionaries would do all they could in helping forward the work

Dr C M WENYON said that much good work had resulted from the central organisation allotting certain work to people specially appointed Perhaps the scheme set out by Dr Stanton would eventually become international An offshoot of the League of Nations organisation was at present conducting a research in Uganda Of course, the highest ideal was to follow science for its own sake, keeping above all human frailty, but for the advancement of knowledge, as human beings were at present constituted, the element of competition perpetuated keen activity In research work it sharpened the critical faculty and led to a further development of the laboratory instinct That spirit was probably answerable for three separate commissions being at present at work on kala-azar

The PRESIDENT remarked that no one had said what was the best type of local organisation for medical research beyond Prof Leiper's suggestion to link it with the medical education side He spoke of the autonomous research work going forward in Trinidad Incidentally, he said that it had been decided to name the Society's new house "Manson House," in memory of Sir Patrick Manson

Diphtheroid bacilli were present in large numbers in the mouth The condition had cleared up, though very bad when he saw it first

Dr GRAY considered the case was more like dermatitis vegetans than true pemphigus vegetans Some of the conditions to which the former name was given were simply fungating granulomatous lesions, without bullous or pustular formation

Dr H G ADAMSON said that one point against the diagnosis of pemphigus vegetans was that the patient had had iodide of potassium If this drug was given to a patient who had pemphigus it always made the bullæ worse, it even brought bullæ out where they were not evident before In one or two cases he believed pemphigus had been started by the local application of tincture of iodine

Dr LITTLE showed a case of

Dermatitis Herpetiformis

The patient had an acute eruption of vesicles on the chest back and buttocks In South Africa he had had three injections of his own blood, and temporary improvement followed them Relapse, however, occurred and the patient was advised to come to this country He now had large bullæ and very characteristic lesions in the mouth, with some old scarring. the result of former lesions He could produce vesicles in a short time merely by exerting pressure on the skin Five minims of liquor arsenicalis thrice daily had brought about a great improvement in the eruption

Dr GRAY was inclined to think that the condition was pemphigus foliaceus, the question could be put to the test by trying to elicit Nikolsky's sign

Dr HEATH spoke of a similar case under his care which was kept under control by means of arsenic

New Inventions.

ELECTRIC-HEATED RADIUM WAX-KNIFE

RADIUM when applied at a distance from the skin in inoperable and post-operative cancer work, according to the principles of Regaud, of Paris and other continental workers is supported by means of wax moulds fitting over the part The construction of these involves considerable manipulation, and to facilitate this the electric wax-knife has been designed Repeated heating of an ordinary wax-knife is both tedious and unsatisfactory The wax-knife shown is kept constantly hot by means of an electrical resistance surrounding the upper part of the blade The current (240 volts) is obtained from the ordinary room supply through an insulated wire with socket The illustration shows the instrument in use It can be obtained from the Medical Supply Association, 167, Gray's Inn-road London, W C.

Reviews and Notices of Books.

VENEREAL DISEASES

Treatment of Venereal Diseases in General Practice. By E T BURKE, D S O, M.B, Ch.B Glasg, V D Officer to the County Borough of Warrington: Member of Council, Medical Society for the Study of Venereal Disease London: Faber and Gwyer, Ltd 1927 Pp 162 5*s*

THIS work sums up for the general practitioner the minimum treatment required and the standard and tests of cure for both syphilis and gonorrhœa Dr. Burke deprecates half-measures in the treatment of either disease, holding that the practitioner who is not prepared to deal thoroughly and intensively with the case from start to a satisfactory finish had better send his patient to an expert for treatment either privately or to the special clinic He gives accordingly seven useful and detailed "schemes of treatment for syphilis," one for each stage or type of the disease. Any practitioner who aspires to treat syphilis well cannot do better than follow these schemes While giving a good chapter on the preparations and modes of administering mercury, the author in his introduction says that he has discarded the use of this drug for over two years, regarding it as "obsolete as is sarsaparilla" The chapter on the treatment of congenital syphilis is excellent, emphasis is laid on the necessity of continued treatment and observation of these cases. The section of the book on gonorrhœa is modern and sound; the danger of making gonorrhœal neurasthenics is mentioned, but at the same time the need is insisted on for careful treatment When the patient appears to be cured observation over a period of time is highly desirable Dr Burke is a believer in the value of vaccines and of electrargol in the treatment of gonorrhœa and its complications

The *obiter dicta* on syphilis and gonorrhœa at the end of each section are usually sound and often amusing; some, however, are a little cheaply clever and scarcely worthy of the book Seven appendices give in detail the manner of collection of the various materials for pathological tests required in V D work, and there is a final chapter upon urethral dilators It is well worth while for every practitioner to buy this book—for guidance if he is in the habit of treating V.D, but in any case to be able to explain to his patients the length and adequacy of modern treatment of these diseases, and to assure them of the excellent prognosis where treatment is thorough and even enthusiastic.

Les Syphilis Viscerales Tardives Par H GRENET, R LEVENT, and L PELLISSIER Paris: Masson et Cie 1927 Pp 378 Fr 32.

THE authors believe that many cases of late syphilis occur owing to insufficient treatment of early syphilis by those doctors who rely on a negative W R as proof that infection is non-existent They quote Scholz-Sadebeck, of Breslau who finds that all cases of syphilis that have been adequately treated with mercury from 1900 to 1921 show a much smaller proportion of tertiary syphilis than was formerly seen; they believe that with the now general administration of salvarsan there should be an even smaller number of tertiaries in future. The authors find that in visceral scleroses syphilis plays an essential but not an exclusive part, and that among other associated factors alcoholism is particularly active The third chapter contains an admirable description of the macroscopic and microscopic findings in tertiary syphilis Long and detailed accounts are given of the various heart lesions of late secondary or tertiary syphilis stressing the variety of the effects of the spirochæte on the heart muscle valves, and blood-vessels A separate chapter is given to aortitis We are also reminded that though aortitis is found frequently from 12 to 20 years after the date of infection yet it is probable that the lesion is often present but causing no gross symptoms at a much of the cervix There was often too much reluctance to try manual dilatation

Mr F OXLEY referred to a case in which the cervix had come away after a strong dose of pituitrin

The PRESIDENT said he thought the accident in this case was largely due to the narcosis, which enabled a patient to stand a great deal of pressure without any reflex disturbance.

Mr PHILLIPS, in reply, said he had often performed manual dilatation of the cervix, but never with the head in the pelvic brim It was quite difficult enough to diagnose some conditions vaginally, and by rectal examination they were sure to be missed

A Theory of the Decidual Reaction

Mr EVERARD WILLIAMS, in describing a patient in whom pregnancy had twice occurred in the tubes, brought forward the new theory that the formation of decidual cells was the primary event and that it determined where the ovum would be embedded This theory explained why normally the ovum was embedded in the uterus and how it was that decidual cells were found elsewhere, present theories failed to do this Ovarian pregnancy was much more common than was at one time believed, and a decidual reaction had been recorded in the peritoneum, the ovary, and the Fallopian tube, in a subperitoneal fibroid and further afield

Dr T WATTS EDEN said that the so-called decidual cells found outside the uterus were simply enlarged connective tissue cells, and not comparable to the true decidual reaction, which included enormous hypertrophy of the whole membrane and glandular and vascular changes

SECTION OF DERMATOLOGY

A MEETING of this Section was held on May 19th, Dr J H SEQUEIRA, the President, in the chair

Dr LOUIS SAVATARD (Manchester) read a paper on

Ichthyosis and Cancer of the Skin,

with special reference to mule-spinner's cancer He said that xeroderma pigmentosum could be regarded as a precancerous dermatosis, as in this rare disease the supervention of cancer was the rule, but the fact that xeroderma simplex, or ichthyosis simplex, was also a fertile soil for malignant growths was insufficiently recognised Ichthyosis he regarded as an important factor predisposing to cancer of the skin In some cases of cutaneous cancer, by adopting a routine examination of the whole skin, he had found lesions unsuspected by the patient, and in a number there was associated ichthyosis, especially where a carcinoma had arisen on a keratotic condition The keratosis was probably secondary to the ichthyosis All types of carcinoma might develop on keratosis, indeed, keratosis was the first clinical sign of a squamous carcinoma Dr Prosser White, of Wigan, had described in mule-spinners a condition of the skin which he had named "shagreen skin," but Dr Savatard had not noticed this peculiarity among the mule-spinners of Manchester whom he had seen, and submitted that this type of skin was merely an ichthyosis Ichthyosis seemed to be fairly common in Lancashire, in an examination of 400 operatives he had found an incidence of 5 per cent Among 400 mule-spinners of very variable ages whom he had inspected at their work he had found 20 with ichthyosis, in 10 of whom the condition was well marked Two had suffered from cancer of the scrotum His investigation had convinced him that ichthyosis was an important ætiological factor in mule-spinner's cancer, and he regretted that the Departmental Committee had stated, after its 1925 inquiry, that without exposure to mineral oils there would be no mule-spinner's cancer Dr J Robertson, of Darwen, had arrived at a very different conclusion after independent inquiry

Dr A WHITFIELD thought that Dr Savatard ascribed an undue importance to ichthyosis, though admittedly the ichthyotic skin was a badly nourished skin, especially in the absence of true maturity of the horny cell and formation of grease The ichthyotic patient started life with that aspect of senility He had not seen malignant keratosis in the keratotic subject

Dr GRAHAM LITTLE said he would have thought it rare for carcinomatous changes to occur in senile keratosis

Dr H MACCORMAC said it had always seemed to him that there was a tendency for the prickle-celled type of cancer to originate in some definitely pre-carcinomatous condition In some cases he saw during the war, particularly in Australians, cancer had developed on exposed sites following long periods in tropical sunshine Senile keratosis was a term which was applied by different dermatologists in different ways

Dr A M H GRAY said it should be an easy matter to determine how many cases of scrotal carcinoma occurred in men who did not work with oils, tar, pitch, or soot He believed it was rare to find scrotal carcinoma unassociated with those occupations

Dr SYDNEY THOMSON said that among many ichthyotic patients he had not seen a warty growth of any sort Ichthyosis had a well-marked topographical distribution, but senile skin had not

Dr H W BARBER said that a point worthy of consideration was the association of multiple superficial basal-celled carcinoma with psoriasis, as pointed out by Dr Gray and Dr Little He asked whether psoriasis were more likely to occur in dry-skinned people than in those whose skin was normal

Dr SAVATARD, in reply, said he recognised that oil, tar, and soot produced cancer, but if careful examination of the whole skin were carried out as a routine he thought cancer would be found more frequently in persons having an ichthyotic skin

Dr. J M H MACLEOD showed a patient who had

Dermatomycosis due to Monilia

He had brought the case, he said because it was important to report such a condition when its true nature had become certain, there was much confusion about the dermal states produced by yeast-like organisms

This woman had, between two or three of her fingers, white patches a quarter of an inch across, which were sodden, as in trichophytic infections At first Dr MacLeod attributed the condition to epidermal trichophyton The scrapings from it showed mycelial shreds, they were coarse and did not branch, and hence he became suspicious as to the correctness of his diagnosis The organism turned out to be monilia At a temperature of 25° C it formed within 18 hours a whitish or creamy glistening culture, later becoming almost granular In the early cultures no mycelia were seen, but there were oval bodies, some of them inclined to bud Later there were small mycelial shreds and small round bodies The culture did not ferment lactose, but in glucose fermentation occurred after a week with production of gas

Dr MacLeod had satisfied himself he said, that the organism was not *Oidium albicans* The monilias were able to produce cutaneous lesions which were indistinguishable from those of true ringworm, but the organisms were very different It was likely that many conditions attributed to yeasts were due to monilia

Dr S E DORE demonstrated a case of what he regarded as

Pemphigus Vegetans

A woman, aged 59, had condylomatous growths on both lips, beginning five months before There was no history of any previous formation of vesicles or blebs The lesions developed before any drugs had been taken, but the patient afterwards took potassium iodide and arsenic The Wassermann reaction was negative, and constitutional symptoms were absent As the patient came from a distance he had not had a biopsy done nor scrapings examined

Dr A D HEATH (Birmingham) spoke of a case of his own, looking very similar, which proved to be one of Hallopeau's disease (possibly dermatitis vegetans) There were also lesions of the nails.

post-mortem examination Armstrong was arrested, convicted of murder,[1] and hanged He had been an extensive purchaser of arsenic, ostensibly for weed-killing. A packet containing 2 ounces of arsenic was found in a bureau drawer at his house; a fatal dose wrapped in paper, was found in his pocket on his arrest, and his explanation—that he had made up an ounce of white arsenic into 20 small packets for the purpose of killing dandelions—went far to damage his defence, elicited as it was in reply to a few final questions by Mr. Justice Darling just before the accused man left the witness-box The defence was unable to controvert the evidence of arsenical poisoning, but suggested that Mrs Armstrong had deliberately poisoned herself though the proof of her physical incapacity during the last few days of her life was incompatible with the suggestion A witness for the defence, Dr. F. S. Toogood, presented the theory that Mrs Armstrong had suffered from auto-intoxication when she went into the asylum that arsenic had nothing to do with her then condition, that she took one poisonous dose on Feb 16th and that part of it became encysted—this being the explanation of the delay in the arsenical action upon the parts of the body where it was found at the post-mortem examination. The main legal difficulty in the case was the question whether evidence of the attempt to poison Mr Martin could be given on the charge of poisoning Mrs Armstrong Mr Justice Darling admitted it and the Court of Criminal Appeal upheld his action. The evidence of the attempted poisoning of Mr Martin was not admissible to show that Armstrong was in the habit of poisoning people and might therefore be expected to have poisoned his wife: but it was admissible in order to show that his purchase and possession of arsenic was not for the innocent purpose of destroying weeds (as he had alleged) but for felonious use upon human beings

Mr. Filson Young writes a bright introduction to this trial which is in some respects not of the most notable. He gives hints that other illnesses and sudden deaths in the neighbourhood might have been ascribed to Armstrong's hospitality. The story has not a little medico-legal interest, though in places it is told with a rather exuberant journalism; the inclusion of Appendix B, for example, is hardly justified

CLAIRVOYANCE AND MATERIALISATION

A Record of Experiments by Dr Gustave Geley. Translated by Stanley de Brath, M.Inst C E London: T. Fisher Unwin Ltd. (Ernest Benn, Ltd.) 1927 With 51 illustrations and 105 diagrams. Pp 401. 30s.

In an address before the International Congress of Physiologists at Edinburgh in 1923 Prof Charles Richet entered a plea for the enlargement of the study of physiology by other means than the ordinary channels of the senses, and this work might form a text-book or guide to experimentation in accordance with the lecturer's thesis Anyhow, Dr. Geley's translator describes him as 'Sceptical in analysis tireless in research, scrupulous in statement fearless in pursuit of truth . . .'—qualities which should fit him to scrutinise the experimental research on the supernormal recently undertaken at the International Metaphysical Institute in Paris In an introduction discussing the practical side of mediumship, Dr Geley deals with the conditions necessary to the production of phenomena, admitting the failure of attempts to solve the difficulty of using the senses of touch and sight in the absence of light, and light is said to have an inhibiting effect on the production of 'spirit forms" He believes that this difficulty may be overcome, but until it is, the sceptic must not be blamed if he refuses to accept the happenings in the séance room as scientific phenomena

The book is divided into two parts one dealing with clairvoyance and the other with materialisation—the so-called ectoplasmic appearances—and in both sections the author describes the procedure at séances and the care taken to avoid fraud: he eschews theorising, save where he gives what he holds to be analogous facts in biology as furnishing possible explanations. To describe the experiments is the main task which he sets himself, holding that 'experimental details do, in fact constitute scientific material which must, willingly or unwillingly, engage the attention even of those most prejudiced against metaphysic studies." He admits that he has not been personally fortunate in seeing complete materialisation of actual beings having for the moment all the characters of life, but claims to have seen fingers with nails, hands with bones and joints and a living head, to have felt a skull under thick hair and to have detected living human faces The writing suggests that he believes that he has had these experiences It is suggested in the book that ectoplasmic forms are a physical duplication of the medium materialised during trance, in which case one would expect to find that wax moulds of ectoplasmic hands and feet which are discussed, would be duplicates of the moulds of the hands and feet of the medium, a clear opportunity for trickery thus being provided in the teeth of much protest as to the impossibility of faking. A sequel to the work, in which an explanation of psychic phenomena on philosophic lines was promised, is lost to the world for Dr. Geley was killed in an aeroplane accident in 1924. He was a serious worker along the lines which he chose and real knowledge is, perhaps, not served by refusing to recognise the energy that is being devoted to various forms of psychical research. Yet the sterility that attends the work of the "spiritualists," even more than their romantic conceptions of "science," makes the reading of the procedures at séances unprofitable.

NEUROLOGICAL DIAGNOSIS

Leitfaden der Neurologischen Diagnostik. Second revised and enlarged edition By Dr. Kurt Singer, Nervenarzt, Berlin Berlin and Vienna: Urban and Schwarzenberg. 1926. With 34 illustrations. Pp. 246 M 9

Dr. Kurt Singer's handbook of neurological diagnosis was reviewed by us at the time of its original appearance, and its practical merits emphasised. With commendable brevity the author manages to provide a conspectus of the whole clinical field of neurology without sacrificing essentials His method consists in the selection of outstanding clinical symptoms (muscular atrophy, paralysis, disorders of gait, involuntary movements, neuralgia, headache, vertigo, unconsciousness and so on) just as they are prone to be encountered in practice, and in analysing the significance of their diversified appearances. In addition to symptom examination he takes the student through sign examination—e g., those furnished by the reflexes and by reflex reactions On every page there is evidence of careful clinical observation and of sound knowledge of diagnostic principles and in its enlarged edition the book is sure of increasing appreciation

TRAVAUX ET MÉMOIRES

By Prof. Pierre Marie. Vol I. Paris: Masson et Cie 1926 Pp 358 Fr 30

The veteran Prof. Pierre Marie has been persuaded to reissue in volume form those now somewhat old, and for that reason (among others) classical, contributions of his which in their time either formed entirely new additions to neurological doctrine or served to orient neurological thought into channels subsequently proved to have led to fresh accretions to its sum-total. They are thus of historical interest and value, and they can be re-read to-day with profit if no longer with the fascination inseparable from their first appearance.

Here is the list: aphasia acromegaly, spondylose rhizomelique, chronic hypertrophic pulmonary osteo-arthropathy, hereditary cleidocranial dysostosis, achondroplasia in the adult Time has confirmed the earlier date. Cases are quoted of undoubted aortitis in syphilis which has been under observation from the start, where this lesion is found at the end of the first year of infection or second years. The authors urge that in old-standing cases of syphilis percussion of tendon-reflexes, examination of the pupils, a Bordet-Wassermann test, auscultation of the heart, and a skiagram of the aorta are all equally important. They emphasise the fact that aortitis is found above all in untreated or badly treated cases of syphilis.

---

[1] The Lancet 1922, i., 812

There are chapters on blood alterations in late syphilis, on infection by syphilis of the lung, intestine, kidney, peritoneum, pancreas; there is also a chapter on the relation of syphilis to diabetes, and another on syphilis of the endocrine glands. Modest in appearance and price, this book will be of value, not only to the worker in syphilis, but to the general physician. It is a patient and exact piece of medical literature.

DISEASES OF THE SKIN

Third edition. By OLIVER S. ORMSBY, M.D., Professor of Dermatology, Rush Medical College, University of Chicago. Philadelphia: Lea and Febiger. 1927. With 521 figures in text and three coloured plates. Pp. 1262. $11.

THE third edition of this important text-book will be especially welcomed by the English-speaking dermatologist, for it contains an up-to-date bibliography most fairly selected from the best literature of all countries. It is difficult to find any weak spot. The size is handy, the paper and printing of good quality, the text concise yet eminently digestible, and the photographic illustrations of typical cases are of unusual merit. The symptomatology of the various diseases occupies by far the largest share of the available space, but this is not to say that differential diagnosis and pathology are neglected. The author has been wise in referring the reader to original sources for information and detail in the matter of treatment in every case where this is not yet standardised, for much space is thereby saved, and the risk of confusion from too generous a choice minimised. The method of classification is that first introduced by Hebra and since adopted by the majority of the writers of text-books. It is based on pathological effects (visible or microscopic)—e.g., hyperæmias, hæmorrhages, hypertrophies, &c.—and is probably the best until all or most of the ætiological demands can be satisfied. There are three coloured plates, but these might as well have been omitted, for they are not true colour reproductions and do not compare favourably with some of the best modern efforts in this direction.

There is an excellent index of over 30 pages, and no serious student of dermatology need hesitate to purchase the book, but it is to the experienced practitioner that it will make most appeal.

Outlines of Common Skin Ailments. By T. CASPAR GILCHRIST, M.D., Professor of Dermatology, Johns Hopkins University, U.S.A. London: Baillière, Tindall and Cox. 1927. Pp. 54. 7*s*.

THE central purpose of this short publication is to assist the student or the practitioner in consulting larger text-books. The method suggested includes a routine of making three cross-references for any particular case, in the following manner: (1) refer to the scheme for making a complete clinical examination given on p. 6; (2) then turn to pp. 9–11, on the regional distribution of common skin diseases; and finally (3) consult pp. 15–35 for "short diagnostic descriptions arranged according to their primary lesions." A system based on the principle of cross-references is seldom a time-saver, while the information contained in the text is too abbreviated and compressed to be of use to any but lecturers or students preparing for their ordeals. There are some 60 photographs illustrating the commoner diseases of the skin; these are much too small to be of any real value as diagnostic aids.

The idea of the book is praiseworthy and well elaborated, but its employment must not be pressed too far, especially by readers with only an elementary knowledge, for whom presumably the book is designed.

NEW STUDIES OF TUBERCULOSIS AND RESPIRATORY DISEASE

Nouvelles Études Cliniques et Radiologiques sur la Tuberculose et les Maladies de l'Appareil Respiratoire. By ÉMILE SERGENT. Paris: Maloine. 1926. Pp. 537. Fr. 65.

THIS book is a suitable companion volume to the collections of essays published by Prof. Emile Sergent some few years ago, entitled respectively Études Cliniques et Radiologiques sur les Maladies de l'Appareil Respiratoire and Études Cliniques sur la Tuberculose. More than three-fourths of the present volume deals with various aspects of tuberculosis, the remainder being devoted to other respiratory diseases. The former comprises pathological anatomy, the rôle of the soil, adolescence, and syphilis in relation to tuberculosis, with chapters on physical signs and diagnosis, tuberculosis of certain special types such as hilum disease and pleurisy, and treatment and prophylaxis. The latter covers rather sketchily abscess of lung, intrathoracic tumours, asthma, non-tuberculous pleurisies, and the condition of which the author has for many years made a special study, syphilis of the lung.

Like the previous volumes, the book is a collection of essays and is in no sense a systematic text-book. The chapters are made up of collections of papers written by Prof. Sergent to French scientific journals, communications to the Académie de Médicine, and discussions at tuberculosis conferences. For this reason, perhaps, they lack the continuity of an ordinary text-book and are valuable, rather, as the personal views of an indefatigable worker in the domain of tuberculosis and respiratory disease. The views of the author on the frequent and intimate relationship between syphilis and pulmonary fibrosis are well known. The chapter on the use of lipiodol in the radiological diagnosis of respiratory disease is valuable and will be found so to those who wish for a detailed description of the technique and results. The illustrations throughout are beautifully done, as are the coloured plates. It is a pity that the book contains no subject index and that the bibliography is so inadequate.

NOTABLE BRITISH TRIALS

Herbert Rowse Armstrong. Edited by FILSON YOUNG. Edinburgh: Wm. Hodge and Co. 1927. Pp. xi + 396. 10*s*. 6*d*.

IN August, 1920, the wife of Herbert Rowse Armstrong was certified insane and placed in Barnwood Private Asylum, near Gloucester. In the following January she was brought home again, but soon fell ill. In February she suffered from acute and constant nausea; on the 18th she lost the use of her limbs and was unable to get out of bed; on the 22nd she died. In the following October Armstrong, who was a solicitor at Hay in Brecon, where he held the post of clerk to the justices, was engaged in a small controversy with another local solicitor, Mr. Martin, over the completion of a sale. Armstrong frequently pressed Mr. Martin to come to his house for tea. On Oct. 26th Mr. Martin did so and was violently ill that night. A sample of his urine was found to contain arsenic. It subsequently occurred to the doctor, who had also attended the Armstrong household, that Mrs. Armstrong's symptoms—vomiting, the "high steppage" gait, and discoloration of the skin were all characteristic of arsenical poisoning. The Home Office was addressed; Mrs. Armstrong's body was exhumed and was found to contain 3¼ gr. of arsenic, the largest amount which the late Mr. J. Webster, F.I.C., had ever discovered upon a

THE LANCET.

ONDON. *SATURDAY, MAY 28, 1927.*

DRUG STANDARDISATION

last two decades have seen a tremendous e in the quantity and diversity of proprietary Synthetic remedies have multiplied, vaccines ra are sold by private firms on a scale which beginning of the century would have been ered incredible, and during the last few years has appeared a whole new range of gland nces unknown in the catalogues of 20 years

Our remarks refer to products which follow scientific investigations conducted at properly ped laboratories or centres of research, so that eps taken are comprehensible to other workers rapeutic treasury is being thus amassed, the of patient and active research, forming a con- and encouraging reminder of the creative vigour informs medical science to-day The store is added to rapidly and, like every growing thing, s continual watchfulness to keep it within the ds of practical utility Sound guidance is hal to protect the practitioner and the public disappointment or worse, and to unify and then the efforts of investigators and manu- ers for the general good Standards, fixed by best qualified in pharmacology, should serve ouble purpose of eliminating the products of who place their own advantage above that community, and of increasing the value of a product by exactly determining that value and g it to the value of similar preparations

international standardisation of drugs is one departments in which the League of Nations forming effective and unobtrusive work in the ts of public health Two conferences have been held under the Standardisation Com- n of the Hygiene Committee of the League at the strands which the war cut through have e-woven and a foundation has been laid for ng of criteria for some of the most important eutic substances As is fitting, the standards RLICH have been adopted for diphtheria and antitoxin, while on the Copenhagen Institute ed the responsibility for conserving them[1] y is to guard the purity of salvarsan through n of Georg and Speier in Hamburg, and that of small pox vaccine, the test being vented some years ago by GROTH and GINS ndardisation Commission is still working on umococcal and antimeningococcal serum, treptococcal antitoxin, a task to which recent n research on scarlatina has given especial nce Apart from the efforts of the League, ernments of many civilised nations are ng independent inquiries The DIVISION of ology of the Hygienic Laboratory of the U S Public Health Service is giving attention to a group of products for which chemical tests are not commercially practicable with a view to standardising them biologically; the group includes the arsphenamines, insulin, digitalis, and pituitary extract The results for pituitary and arsphenamine have already been adopted by the editors of the United States Pharmacopœia[2]

We summarised in a recent number[3] the new regulations under the Therapeutic Substances Act They form a fairly complete legislative filter for proprietary drugs, but would form a much better one if the necessary knowledge were available Perhaps the time is not yet ripe for subjecting all drugs of whatever kind to a legally established potency and purity test The makers with great names, who have always shown themselves staunch allies of medical science, can be trusted to do everything to perfect their products, and official safeguards would be a negligible stimulus in comparison with their zeal for personal reputation Less scrupulous or skilful manufacturers are bound in the course of time to find their goods in little demand However, in the absence of national or international standards there is no means of relating the potency of a given product from one factory with that of the same product made in another, a handicap alike to manufacturer, clinician, and experimenter. The regulations fix a standard for pituitary extract, but none for ergot or thyroid, not to mention a host of other examples which will readily occur to mind. It is to remedy what is admitted by all to be a dangerous and unsatisfactory state of affairs that the Advisory Council of Scientific and Industrial Research contemplates setting up a joint organisation with the Medical Research Council for undertaking research on the production of drugs and "allied problems," of which standardisation will undoubtedly be one, and for promoting similar research in universities and the chemical industry The grounds for this decision are given in a brief but pregnant passage of the recent report[4] of the Advisory Council "As matters stand now, a private firm or individual may develop a new remedy which preliminary trials indicate may be useful in the treatment of disease, but it is impossible to get such a remedy exhaustively investigated by a competent authority The comparative lack of scientific knowledge of the real action of different chemical substances on the human body also hinders the development of medicine" The project is at present being discussed by a joint committee It is, however, to be hoped that the ultimate scope of the new body, if and when it is materialised, will be much wider than that indicated Chemotherapy is important enough, but unless the field of biotherapy is included as well, the venture will be seriously incomplete Since the action of so many chemical substances can only be ascertained by biological experiments, the apparatus necessary for the latter class of research would be available in any case, and it may be that the Councils have already decided not to confine themselves to the study of pure chemotherapy If this is so, it would be hard to mention a department of study on which public money would be better spent, and the sooner work is started the better Something definite and concrete would then have been done to solve a problem that becomes more urgent every year views expressed many years ago in most instances, if not in all; yet confirmation or modification counts relatively little in comparison with the evidence these pages furnish of the clinical method carried to perfection, of clinical insight tinged with genius, of clinical observation proceeding to its conclusions without waiting on the laboratory or the post-mortem room. Not that either of the latter is ignored or belittled—the exact contrary is the case; but the first step in advancing knowledge must ever be taken by the study of living material and by the correlation of clinical instances. Of this method Prof. Pierre Marie has been the master, as, in another sense, he has been and is still the "Maître" of a whole generation of neurologists scattered the world over.

WHEELER'S HANDBOOK OF MEDICINE

Eighth edition. By WILLIAM R. JACK, B.Sc., M.D., F.R.F.P.S.G., Honorary Consulting Physician to the Glasgow Royal Infirmary. Edinburgh: E. and S. Livingstone. 1927. Pp. 630. 12s. 6d.

"Wheeler and Jack" is now well known as one of the best synopses of medicine available as a handbook. It is a stand-by alike to the student and practitioner. The eighth edition has been rendered necessary by the exhaustion of the seventh since we reviewed it in 1924. There have been few changes in medical practice and theory during this interval requiring new articles, but the whole book has been revised to include the most recent work in pathology and treatment. It is the care taken to keep this work up to date that makes it a valuable possession.

NOTES ON MALAYAN CULICIDÆ

By A. T. STANTON, M.D., F.R.C.P., D.P.H. London: John Bale, Sons and Danielsson, Ltd. 1926. Pp. 94.

THIS volume of collected papers by Dr. Stanton, who is a well-recognised authority on the entomology of Malaya, forms one of the series of studies which have recently emanated from the Institute for Medical Research, Kuala Lumpur. Amongst the papers included are several concerning the larval characteristics of Malayan anophelines, notes on the anopheles of Malaya and Sumatra, and records of malaria infections amongst them. The text is embellished, and the descriptions rendered clearer, by the very effective black-and-white drawings of Mr. Engel Terzi and Miss Ruth Ford. The gradual collection of data of the various forms of mosquito that carry parasites in different parts of the tropics is an important part of the world campaign against malaria, and we welcome the efforts being made in Malaya to investigate and differentiate species and their habits.

MEDICAL NOTES

By W. J. TYSON, M.D. Durh., F.R.C.P. Lond., F.R.C.S. Eng. London: H. K. Lewis and Co. 1926. Pp. 64.

THE busy consultant rarely has time to analyse and correlate observations made here and there on all sorts of conditions, and he often hesitates to make public the contents of a scrappy note-book, even if he has been wise enough to keep one. Dr. Tyson, however, has bravely issued a small book containing 50 short notes jotted down at various times. The value of these "stray thoughts, gathered from long hospital and private experiences," is great, for they form records of experience but little influenced by text-books or fashionable views. Notes on such subjects as "syncope from biliousness," "the soporific action of mercury," and "the danger of putting old people to bed" are hardly to be found except in collections such as this. Dr. Tyson makes some useful suggestions on the treatment of the relations and friends of patients; he adds: "I have often thought that the public do not always realise or understand what a professional fee includes. It means not only the direct treatment of the patient, but also the thought for the future welfare of the patient at times when the doctor is at home, and also the interviews, letter-writing, and telephone messages by the relations. It is well sometimes that the public should be informed of these matters." He concludes with an apt note on "when should we as doctors—or our patients—give up work?" Dr. Tyson's book gives one the pleasant impression of having had a chat with him on "shop" by the fireside.

THE STRUCTURE OF THE ATOM

Third edition, revised and enlarged. By E. N. DA C. ANDRADE, D.Sc. Lond., Ph.D. Heidelberg, Fellow of University College, London, and Professor of Physics in the Artillery College, Woolwich. London: G. Bell and Sons, Ltd. 1927. Pp. 750. 30s.

THE third edition of Prof. Andrade's book is a very much bigger volume than the first, and is probably the most complete exposition of the subject at the present time. The book is written for those who want to get definite information on the subject of atomic structure; this information reveals the atom to be of *great simplicity in some respects and in others of* great complexity. The simplicity of structure whereby practically all the mass of an atom is concentrated into its nucleus appeals to anyone who is looking for *an explanation of how it is that alpha particles on* impact with such atoms are sometimes swung back upon their paths, but this simplicity has to be disregarded directly the spectral characteristics of the atoms are discussed; the structure which spectroscopists require in order to give a rational idea of line and band spectra appears to become more and more complex. Experimental and theoretical treatment run side by side in this book, and physicists are under a deep obligation to Prof. Andrade for the masterly way he has tackled both aspects of the subject.

HOMINICULTURE

Organisation et Hygiène Sociales. By Dr. JULES AMAR. Paris: Dunod. 1927. With 110 text figures. Pp. 692.

IT is generally supposed that the time has long gone by when a man could take all human knowledge for his province and write books about it. If it has, Dr. Amar makes a good attempt to revive it. His book is described as a treatise on eugenics or, as he prefers to call it, hominiculture; it might well have been titled *De omnibus rebus et quibusdam aliis*, which is perhaps not an unreasonable synonym for any comprehensive discussion of all that makes for the betterment of the human race. He treats successively of the history of social hygiene, the immense importance of the discoveries of science, the colloidal nature of living matter, immunity, probability and statistics, reproduction and generation, heredity, growth, adolescence and celibacy, education, alcoholism, syphilis, cancer, tuberculosis, old age, death and nationality, with odd notes on everything from Jenner's treatment of his domestic servants to the size of the spleen in sticklebacks. He quotes his authorities profusely and they range from Genesis to Loeb, and from Willard Gibbs to what Lady Astor is reported by the daily press to have said. The whole is written with a captivating vivacity and certainty; the author has clear views on all subjects, and he expresses them plainly. It is impossible to review such a book. It may be felt that no man could cover such a field with anything like tolerable accuracy; as a matter of fact, testing those parts of the book which are within our knowledge, we find that the author does not stray far from what we believe to be the truth. Previous works by Dr. Amar on scientific management, industrial efficiency, and the employment of disabled men have been translated into English and several other languages. This one may be equally popular; it is certainly a remarkable performance and must be almost without rivals for use on a desert island.

harmful. Seeing that conception can be avoided by numerous methods (those in commonest use are abstinence, restriction of intercourse to "safe" periods, coitus interruptus the sheath, the vaginal douche after coitus. various kinds of soluble pessary and sponge or rubber occlusive devices). it is at least possible that these methods may vary in the degree to which they cause harm and though a general survey of the subject designed for the lay public may not lend itself to any detailed discussion of the various methods in use, it is equally obvious that medical men and women must consider the possible effects on health or the production of sterility by each method separately before they can safely generalise. The commonest medical arguments used against birth control are that contraceptives cause sterility, genital disease. and psychoneuroses, and they are useless in preventing conception The degree if any, to which different contraceptives offend in these ways is capable of statistical formulation. Certain material for statistical treatment of the subject already exists Through the Walworth centre of the Society for the Provision of Birth Control Clinics over 8000 women have passed.[1] Through Mrs. Marie Stopes s centre at Holloway 5000 patients had passed at the beginning of 1925,[2] and in the near future doubtless further material will be available No statistical records are discussed in the essays

Sir Arthur Newsholme's treatment of the problems arising from the declining birth-rate is clear and convincing Likewise the original evidence adduced by Sir John Robertson of the nefarious influence wielded. in industrial districts by manufacturers of contraceptives who wish to provide markets for their goods Also of great interest is the contribution by Dr Letitia Fairfield Referring to the measure proposed recently in the House of Commons that local authorities should be empowered to increase expenditure, when deemed expedient, in conveying knowledge of birth control to married women who desire it, Dr. Fairfield argues that. if carried this measure might result in the disintegration of the maternity and child welfare movement. "Of the 2112 clinics," writes Dr Fairfield, "at work in 1925. 756 were voluntary. and in the maintenance and running of the latter. religious individuals and organisations play a prominent part. Not the least of the triumphs of the maternity and child welfare movement has been its unique influence in drawing together women in all classes and creeds in the service of the baby With the coming of birth control all this happy coöperation will at once be a thing of the past and the movement will be split from top to bottom. The cleavage would necessarily extend beyond the managing committee the staff and the subscribers. and would affect the patients and the reputation of the clinic (p 122) Dr. Fairfield also believes that if difficult economic conditions are to be held to provide justification for giving advice on conception control to women the decision as to whether a given woman should or should not receive such advice cannot rest with the doctor alone She points out that once the indications for use pass from medical to economic grounds the discretion can no longer lie with the doctor whose opinions on such matters have no special value. If birth control is a legitimate remedy for poverty, it is only reasonable that those who feel the pinch should have the deciding word Nor is it the least likely that Mr and Mrs. X will accept dictation as to the number of children they can afford on their wages from a young Dr. Y sitting at a clinic, and acting on the report of Nurse Z. Both these arguments deserve careful consideration. The attitude hitherto adopted by the Ministry of Health towards this measure, as it was proposed in the House of Commons. has been one of official opposition qualified by unofficial concessions (vide the Archbishop of Canterbury's speech in the House of Lords, THE LANCET. May 22nd, 1926). of such a nature that many officers in charge of welfare centres do not at present know how much latitude they possess in this matter.

In view of the numerous divergences of opinion expressed by the various writers of this book, attention will be commanded by one point with regard to which there is complete unanimity It is to the effect that the method of coitus interruptus is medically harmful. This contention is stated in exceedingly emphatic terms by Dr. Crichton-Miller. than whom there is no other contributor more competent to speak upon this matter. He says that modern medicine has established beyond dispute that this practice is profoundly detrimental, always to the man and frequently to the woman Another consideration not put forward in the book—that the propaganda of contraceptive manufacturing firms frequently result in women buying occlusive pessaries *that do not fit* and employing them when there are contra-indications to their use—suggests that occlusive pessaries should not be generally used by the community without medical guidance. Suppression of the sale of all contraceptives—supposing that this could ever be brought about—might have little effect on the declining birth-rate But it would certainly result in an enormous increase of coitus interruptus. It might even be argued that other methods of preventing conception have at least this value, that they tend to dispossess coitus interruptus as the method of preference and of "least resistance." In the event of the pre-eminent harmfulness of coitus interruptus being firmly established. considerable medical importance might be attached to this contention.

We understand that evidence is accumulating that occlusive pessaries, when unfitted and when used without medical guidance, are more prone to cause disease than when properly fitted Not only is the danger of cervical and vaginal trauma enhanced by using a pessary of the wrong size. but there is the danger that a disease such as gonorrhœal cervicitis may be present in which case pathological discharges might be retained with serious consequences Both these dangers could be reduced if it could be assured that all women who used contraceptives *did so* only under medical supervision Yet Dr. Fairfield s arguments make it difficult to see how medical guidance can be provided throughout a wider sphere than that covered by the private societies which find clinics for the purpose. A possible solution to the difficulty might be found if the Ministry of Health *were to* leave the decision of whether or no birth control is to be taught at the antenatal and maternity centres—to the committees in charge of these centres and if so, under what circumstances it should be taught. No compulsion either to permit or prohibit the giving of advice on birth control need be brought to bear on these committees On the contrary, the question could be left for them to settle locally, like any other of the numerous questions that arise before them, in accordance with the local requirements and the local outlook. In whatever course he adopted in a given case the doctor. under these circumstances. would be but fulfilling the approved decision of his committee. who would bear full responsibility for the decisions he took In this way there would be no question of the Ministry of Health introducing contraception into the country by a side-door no necessity for a movement *that is partly voluntary* being split by compulsion being brought to bear on it from without and no question of a doctor in the charge of a centre arbitrarily dictating, on his own initiative in a sphere in which he is not necessarily competent to form an opinion to any of the patients who might come to him for medical advice.

THE DISINFECTION OF BEDDING

BEDDING and blankets are particularly difficult to disinfect by heat And this is natural, for as HAMER and HUTT point out,[1] they represent the highest outcome of man s ingenuity in devising material to check the passage of heat Bedding does not suffer to the same extent as do blankets from prolonged exposure to heat, and there is a growing tendency to be content, in the case of bedding, with thorough sunning and airing Brighton, for instance, gave up stoving mattresses 15 years ago without any increase in the number of return cases of the common exanthemata But Margate disinfected more than 600 blankets last year, and blankets no doubt formed a considerable proportion of the 50,000 articles which went through the municipal disinfector at Newcastle-on-Tyne It may be well, therefore, to recall certain experiments on chemical disinfection made by Dr H OSBORNE, medical officer of health of Salford, to which brief reference [2] has already been made The outcome of one set of these experiments was that at blood temperature the disinfecting action of carbolic acid is twice as powerful as at ordinary room temperature and three times as powerful as at freezing-point Dr OSBORNE started from the position that blankets in particular are liable to be greatly deteriorated by exposure to a temperature of 115°–120° in the steam disinfector, although they will suffer less damage when saturated steam is used and the articles are not exposed to great heat in the subsequent drying Many years ago the late Prof SHERIDAN DELÉPINE showed, for the benefit of the Bradford wool industry, that even anthrax spores may be killed by exposure to warmed formaldehyde vapour, and the Salford Health Committee has recently installed an apparatus at Ladywell Sanatorium for disinfecting blankets and woollen articles by the warm formalin vapour process If the desired result can be obtained in this manner there seems no reason why the practice should not be more generally adopted, for one type of disinfector at least can readily be converted into a formaldehyde chamber

It was DELÉPINE also who showed the great increase of efficacy brought about by warming the disinfectant solution The experiments were carried out by Dr OSBORNE under DELÉPINE's direction, and the results appear for the first time in his report A fixed time of exposure to the disinfectant was adopted as convenient—viz, 20 minutes—and the organisms used in the tests were the colon and plague bacilli, the golden staphylococcus, and anthrax spores Both broth cultures and silk threads, soaked in an emulsion of the organism, were tested against carbolic acid With the three non sporing organisms disinfecting power increased proportionately with the heat For example, threads impregnated with the colon bacillus were rendered sterile by 1 40 and 1 50 solutions at freezing-point, by 1 60 and 1 65 solutions at 13° C, and by 1 20 and 1 130 solutions at 36° C Of the three the plague bacillus was the most easily killed At blood heat the colon bacillus and the staphylococcus succumbed in solutions weaker than 1 100 and the plague bacillus in solutions of 1 500 Anthrax spores proved vastly more resistant Thus a 1 50 solution of carbolic took 10 to 14 days to kill these spores at 37° C and four days at 47° C, while a 1 20 solution took 12 to 18 hours at 37° C and three to four hours at 47° C, even liquefied carbolic acid failed to kill in nine days at 18° C, but required only two hours at 37° C and 10 to 20 minutes at 47° C The practical outcome of these experiments is that a comparatively weak solution of carbolic such as 1 100 may be depended upon to kill at blood heat all the non sporing organisms for which disinfection is usually needed In the rare cases where disinfection for anthrax is needed a much stronger solution and a longer exposure will be necessary, or recourse may be had to the warm formalin chamber Now that these results obtained by Prof DELÉPINE and Dr OSBORNE have been published the matter will no doubt be followed up by other investigators using a variety of disinfectants Such a sequel seems eminently desirable

Modern practice tends to belittle the good done by ordinary attempts at fumigation and disinfection of the air of rooms, and to concentrate on the removal of bedding, hangings, and the like, to the public disinfecting station It is therefore the more important that the householder should have confidence that the goods removed will be returned to him intact There is at present a very natural but dangerous tendency to conceal any valued articles of clothing or bedding in order to save them from possible damage We believe that inquiry would show that there is as much room for improvement in methods of disinfection by public authorities as there was found to be in the methods and apparatus used not long ago for the commercial pasteurisation of milk

◆

THE MEDICAL ASPECTS OF BIRTH CONTROL

BIRTH control differs from the great majority of questions upon which the medical profession can claim first voice in that, for most people whether lay or medical, it is intimately bound up with ethical and religious convictions For those persons whose religious beliefs with regard to birth control are fluid, disinterested scientific inquiry with regard to the merits and demerits of the various devices which are employed to avert pregnancy is possible, though it may not always be easy But for those whose intimate beliefs are guided by religious precepts which are uncompromisingly hostile to birth control, a disinterested spirit of inquiry becomes a matter of difficulty, almost amounting to impossibility

It is a peculiarity of human psychology that when a given practice is believed to be morally reprehensible, this practice cannot easily be regarded as, in any sense, generally expedient It is rare to find a person opposing birth control on religious grounds who does not oppose it on all other grounds of expediency as well For these reasons the formulation of an impartial opinion on the purely medical aspect of this question is difficult The author of the critical review of a recent medical compendium of this subject, which we publish on another page, finds unconscious bias in the essays of some of the contributors By most of the writers in the book, which has been hailed *in certain quarters* as a weighty medical condemnation of all forms of birth control, it is conceded that the practice of artificial conception control is justified in cases where the woman is unfit for pregnancy, or tainted with hereditary disease, though this practice is opposed when the woman is merely suffering from economic stress But with regard, in either contingency, to the best method to be employed to avert conception this book is silent, though the majority of the writers are emphatic that the use of contraceptives is frequently harmful Seeing that conception can be avoided by numerous methods (those in commonest use are abstinence, restriction of intercourse to ' safe ' periods, coitus interruptus the sheath, the vaginal douche after coitus various kinds of soluble pessary and sponge or rubber occlusive devices), it is at least possible that these methods may vary in the degree to which they cause harm and though a general survey of the subject designed for the lay public may not lend itself to any detailed discussion of the various methods in use, it is equally obvious that medical men and women must consider the possible effects on health or the production of sterility by each method separately before they can safely generalise The commonest medical arguments used against birth control are that contraceptives cause sterility, genital disease and psychoneuroses and they are useless in preventing conception The degree, if any, to which different contraceptives offend in these ways is capable of statistical formulation. Certain material for statistical treatment of the subject already exists Through the Walworth centre of the Society for the Provision of Birth Control Clinics over 8000 women have passed.[1] Through Mrs. Marie Stopes's centre at Holloway 5000 patients had passed at the beginning of 1925,[2] and in the near future doubtless further material will be available. No statistical records are discussed in the essays

Annotations.

"Ne quid nimis"

ODONTOLOGICAL COLLECTION AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

ON Monday last the President of the College opened the new odontological collection in the Hunterian Museum, a magnificent collection and a great testimony to the devotion of the Odontological Section of the Royal Society of Medicine, and especially to Sir Frank Colyer. In a brief address Sir Berkeley Moynihan sketched the steps which had led to the formation of the collection. This, he said, dates back for 70 years when the leading dental surgeons of the country formed the Odontological Society of Great Britain and began at once to collect instructive specimens for exhibition at their meetings. As a result, when the Odontological Society came to be fused with the Royal Society of Medicine, no less than 5000 catalogued specimens were in charge of an indefatigable honorary curator; this was Sir Frank Colyer, who remains to-day in that position, "displaying," as the President said, "all the energy and enthusiasm and even more than the high competence of 20 years ago." It was recognised by all that this great collection could be regarded as of a national character while serving the particular interests of odontology, and accordingly, in 1908, the Royal Society of Medicine offered the collection in trust to the College, who one year later installed the specimens in their museum and defrayed the accompanying cost. Thus, as Sir Berkeley Moynihan reminded his hearers, to the specimens assembled by the Odontological Society there could be added the Tomes collection and John Hunter's original specimens, described by the speaker as "things of the utmost beauty of workmanship and beyond all price both from their scientific and their historical interest." For all comparative pathologists know that some of Hunter's most fundamental discoveries were the outcome of his study of teeth. The College acceded to the natural representations of the Odontological Section of the Royal Society of Medicine, the heirs of the old Odontological Society, that the Section should continue to take a direct interest in the welfare and growth of the collection, use its contents for their meetings and demonstrations, and advise in its general management, a part of the trust now faithfully carried out by Sir Frank Colyer and zealous colleagues. So that the number of the specimens has grown with amazing rapidity especially in the direction of the comparative pathology of the teeth—an important branch of knowledge which the curator has made peculiarly his own, utilising to the full the splendid material placed at his disposal by the Zoological Society. The President closed his address by referring to the recent addition to the odontological museum of the Howard Mummery bequest, the microscopes, instruments, and the material results of all that great investigator's labours being now ranged alongside of the Tomes collections.

MILK AND VITAMIN D

RECENT experimental work in this country makes it probable that the parent substance of vitamin D, the antirachitic factor, is either ergosterol or a highly unsaturated sterol of similar constitution, which becomes active after it has absorbed ultra-violet light and lost its characteristic absorption band. The antirachitic value of milk varies, as everyone knows, within wide limits, and that of cow's milk—fresh, dried, or condensed—can be greatly increased by exposure to ultra-violet light. Presumably any ordinary cow's milk contains an amount of ergosterol which would be ample to render the milk strongly antirachitic if the sterol were present in the activated form. Now the age at which rickets begins to develop in children is nearly always well under one year, though it may progress if conditions are adverse until the child is several years old. Hence the importance attaching to attempts, such as those described in THE LANCET of April 30th, to raise the antirachitic value of winter cow's milk, the staple foodstuff of nearly all artificially fed infants. An experiment corresponding to that of Dr. J. Golding, Miss K. M. Soames, and Dr. S. S. Zilva has been carried out by Dr. A. A. Weech[1] in Baltimore, human mothers and their infants being the test-objects instead of cows and rats. Dr. Weech made his observations on negro mothers and their breast-fed babies, delivered in the Johns Hopkins Hospital, and attending welfare centres in the city. The prevalence of rickets in breast-fed coloured babies in the United States makes its prevention a very urgent problem. In a series of 260 mothers he endeavoured to get three out of every four to take approximately half an ounce of cod-liver oil daily from the time of confinement onwards, but only 47 of the series of infants were, from one cause or another, available for study when the baby was about six months old in January to May, 1925. Many infants, for example, had been given accessory feeds and were therefore excluded. One point of interest is that, in spite of great efforts on the part of the observers, only 12 of these mothers had received (and presumably consumed) as much as 40 oz. of cod-liver oil in six months, which means a daily average of 2½ drachms or (say) one and a half level teaspoonfuls. This emphasises the fact that cod-liver oil so given is unlikely to be generally used by nursing mothers, though possibly if smaller amounts had been ordered it would have been better taken. A similar attempt at prophylaxis by administering cod-liver oil to the mothers was made by the British and Austrian investigators in Vienna in 1920–1922, but was abandoned on account of the dislike to the oil shown by the mothers. However, Dr. Weech produces radiographic and clinical evidence that the quantities of oil taken in his experiment had a prophylactic value—that is to say, a certain amount of the antirachitic vitamin passed into the milk—though even the larger amounts of oil (48 and 58 oz. in six months) did not ensure freedom from rickets in the child. No indication is given as to whether this medication was fairly evenly distributed over the period of observation. Infants known to have had cod-liver oil directly administered were of course excluded, though the possibility that others of the series *may* have received some cannot be entirely ignored. The radiographic and blood findings—calcium and phosphorus in the serum—show a remarkably close parallel, and both indicate that the average degree of rickets in the children varied inversely with the amount of cod-liver oil taken by the mothers. Three years ago Dr. R. Wagner and Dr. H. Wimberger[2] in Vienna fed rachitic in-patient infants on the milk of cows receiving cod-liver oil in doses increasing from 50 to 300 g. daily during the winter. These children received, it is true, a diet high in carbohydrate; the milk, however, did not prove definitely curative, and it is clear that much more work is necessary before final conclusions can be formulated.

INCREASE OF SYPHILIS IN FRANCE

SOME months ago[3] Prof. Josef Jadassohn, of Breslau, addressed a questionnaire to syphilologists in various countries, and the results indicated that except in France, there was a general decline of syphilis throughout Europe. Similar conclusions have been reached by Dr. Marcel Petit.[4] Both in Paris and in the provinces, he finds, there has been a distinct increase in the incidence of syphilis since 1924 in striking contrast with its decline in other countries. In Scandinavian countries, for instance, the disease is said to have disappeared almost completely. In Switzerland its rapid and continuous decline is shown by the number of primary chancres in Prof. Oltramare s clinic at Geneva having fallen from 104 in 1919 to 2 in 1925 In Belgium likewise there has been a decrease ; in the province of Antwerp, for example the number of primary sores which was 203 in 1920. fell to 10 in the first eight months of 1925 and to nil in the September of the same year. A similar decline was also shown in Spanish statistics This decrease of syphilis is attributed by the syphilologists of the countries in question partly to the fact that State regulation of prostitution has been abolished and partly to the good effects of treatment with salvarsan The persistence of the disease in France appears to be due to two principal groups of causes The first includes factors which have long been in existence—namely, ignorance on the part of the patient and ignorance on the part of medical practitioners. The second group comprises those causes which have come into operation only within recent years—e g the immigration of infected workmen from abroad especially Arabs and Poles the increase of prostitution due to economic conditions and the abandonment of intravenous injections through fear of accidents Dr. Petit urges the taking of energetic measures to stem this rising flood of syphilis

OSTEOPATHS AND THE MEDICAL ACT.

THE vexed question of an osteopath's right to recover fees in the law courts seems to require answer by some tribunal of high authority. A few weeks ago the deputy county court judge sitting at Marylebone entered judgment for the defendant in an action in which an osteopath had claimed £30 9s for fees for treating the defendant s wife for nervous disability and facial neuralgia This decision was based on the familiar language of Section 32 of the Medical Act of 1858, which debars the recovery in a court of law of any charge ' for any medical or surgical advice, attendance or for the performance of any operation ' unless the plaintiff proves at the trial that he is registered under the Act The plaintiff at the Marylebone court had no British medical degree, but had an American degree as doctor of osteopathy. He appealed to the Divisional Court on the ground that he had claimed fees for manual treatment, not for advice given ; he said the defendant s wife, when she first visited him, knew perfectly well the nature of osteopathic treatment His counsel submitted that the circumstances were almost exactly similar to those of an earlier case (Hall v. Trotter) in which it was held that an osteopath could recover fees for treatment rendered The Divisional Court felt itself bound by the authority of Hall v. Trotter (decided in 1921) and sent the case back to the Marylebone County Court for a new trial.

The *facts in Hall v* Trotter are, unfortunately, not very fully reported. It is important to know whether the facts amounted to ' advice " or "attendance ' or "the performance of an operation" within the meaning of Section 32 An osteopath sues on an implied contract to pay him a reasonable sum for the skilled services he renders Presumably the court must satisfy itself of the substantial nature of those services and must not merely accept the description which the osteopath gives to them. It may be, as Mr Justice Acton observed in the recent case, that an osteopath's charges can on analysis be split up into items for advice and items for manual treatment, and that fees can be recovered for the latter and not for the former Presumably the defendant takes the view that his wife went to the osteopath for advice and to obtain such treatment as he might advise It may be that the osteopath replies : "I gave no advice, *or, if I did* I made no charge for it " But even then we are in doubt as to the meaning of "attendance " Is it attending upon a patient *or attending* to a patient ? And is not manipulative treatment (which sometimes involves the breaking down of adhesions or the readjustment of something displaced) an " operation, or can no operation be performed without a knife ? Judges are not likely to construe the word "operation ' in such a manner as to prevent a masseur from recovering his charges And in Hennan v Duckworth in 1904 Mr Justice Wills interpreted the word ' operation " in the corresponding section of the Dentists Act as meaning an operation " in the surgical sense ' going on to decide that an unregistered practitioner might recover a charge for supplying false teeth but not for fitting or filling In Hall v Trotter Mr Justice Horridge breezily declined to be led into definitions He said that the plaintiff (a woman) gave no advice but merely gave certain treatment to the body Mr Justice Shearman, who agreed said she used her knowledge of anatomy to help her to determine the part of the body to which she should apply the treatment she had been specifically called in to give But he added that he was far from saying that anyone who liked to call himself an osteopath could charge for any service which he chose to render. In concurring with Mr. Justice Acton in ordering a new trial in the recent appeal, Mr. Justice Talbot observed that had it not been for the decision in Hall v. Trotter, a very strong argument might have been urged in support of the Marylebone County Court judge's judgment It is to be hoped, therefore, that the Marylebone case will be brought before the highest legal tribunal, so that the legal uncertainty may be removed

SWIMMING BATHS

IT is now 15 years since Dr Graham Forbes called attention *to the dangers of the public swimming bath* in a paper published in *School Hygiene* (1912). Since then much has been written on the subject, especially in America, and at a meeting of the Society of Medical Officers of Schools *on* May 20th Dr Forbes was able to refer to a formidable list of papers recording various infections, minor and major, traced to the public bath He quoted the results of a *questionnaire* addressed to 2000 American doctors in 41 States. 70 per cent of the replies expressed a belief in the positive danger of the bath ; 38 per cent ascribed this mainly to the water and 31 per cent. mainly to the towels and bathing suits Several *definite* and authenticated epidemics were reported—7 of conjunctivitis 9 of diseases of the skin, 2 of otitis media, 2 of tonsillitis, and 1 of sinus infection. Colds and catarrhs were also recorded in large numbers; ringworm typhoid fever, venereal disease, and even poliomyelitis were attributed in *some* cases to public baths. Bacteriological counts had found 4000 bacteria per c cm. of bath water, derived from the skin and saliva of the bathers and from fæcal contamination Although *most* of these organisms are normally saprophytic they are, as Dr. Forbes pointed out, capable of becoming pathogenic under certain circumstances of lowered bodily resistance, particularly the chill following long immersion. In most children the clinical thermometer gives a lower reading after bathing The local effect of chilling the nasal and pharyngeal mucosa must also be considered, as well as the absence in man of the anatomical adaptation to immersion which characterises aquatic mammals and birds The rapid increase in bathers, and the recognition of the dangers involved, have made public authorities consider their legal liability in the event of an infection being traced to their baths In America a very high standard has been set up by the American Public Health Association , bathers are made to take a preliminary wash with soap, and a two-way vertical shower plays down on the head and up between the legs ; they are warned to avoid expectoration and blowing water out of the mouth. Such an interference with personal liberty would never, Dr Forbes feared, be countenanced in this country, although in London baths the attendants are supposed to refuse admission to very dirty children In one only are bathers required to wash themselves first The untreated swimming bath is a shocking sight, as Dr. F W.

Alexander vividly recalled at the same meeting. The water soon becomes like pea-soup, the smell of clothes and towels is overpowering, and on the bottom a slimy mass of hair and dirt collects. Dr. Alexander described the difficulties and successes of his pioneer work on the public baths of Poplar, where the first electrolytic apparatus was installed in 1908. Hypochlorite of magnesium is used there with great success[1] in the proportion of one part of chlorine to one or two million parts of water. The plant consists of five Mather and Platt 30-amp graphode electrolysers, each with eight cells working in series off the council's supply. The total output of the plant is about 300 gallons a day at a cost of approximately 1s 6d per gallon of liquor containing 10 g of available chlorine per litre. Bath water treated with this "electrolytic fluid" keeps clear longer, and is said to be fresher and more invigorating. As Dr. Alexander pointed out, such a method must have as its object the improvement of the water, and not economy in changing. The rule now is that fresh water is supplied after every 1000 bathers, but the matter is not entirely one for rule of thumb, as very often in hot weather the water will suddenly become opaque and dirty; the time of changing must depend on temperature, aeration, and other factors. The reason for this sudden turbidity is obscure. Dr. Alexander ascribes it to an increase in bacteria and organic matter. Electrolytic fluid will not clear it up again.

While chlorination of some sort is a useful practical method, it is generally agreed that the ideal treatment is filtration, aeration, and sterilisation, as carried out in the open-air bath at Harrow, described by several speakers as almost ideal. To keep the water not only bacteriologically pure but also clear, colourless, and attractive means such constant changing of the water that the baths could only be in use for half the time. Many big baths take two or three days to empty, clean, and refill, as Mr. E. C. Wilkinson pointed out in describing the best plants for a continuous system of purification. In the first place, the baths should be so built that they can be easily cleaned, and secondly, they should be lined with white glazed brick or cement, and fitted with a patent non-slip curb and an overflow trough to serve as spittoon and scum-collector, with a spray pipe to drive the scum to one end. The cost of upkeep should be reduced by having as little woodwork and painting as possible. The purification plant should include a battery of two or more filters with an aeration chamber, and a pump with an air compressor. The water is taken through a strainer, and at the same time the chemical reagent is drawn in and mixed with it. It then passes to the filter and thence to the aeration chamber, and finally through a heater. Thus it is continually purified and passed round into the bath again every six, eight, or ten hours as desired. If there are two filters, one can be cleaned while the other is still filtering by a reverse flow of the water—a very important point, since filters soon get out of order if not cleaned regularly. To keep the water bacteriologically safe Mr. Wilkinson recommended the addition of chlorine in some form to the bath at night, while it should also be aerated by the cascade method or by blowing air into it. With such an apparatus it is possible to go on using the same water for a few years, although Mr. Wilkinson thought it wiser to change the water once every 12 months. In his opinion the plant should pay for itself in three or four years, quite apart from the inestimable benefit to the public health. The cost of an apparatus to deal with a bath of 370,000 gallons, passing the whole of the water through in eight and a half hours, would lie between £3000 and £4000 with about £40 per annum for maintenance. To turn out and refill such a bath would take three days each time and cost £230 in the course of a year, so that the outlay on the filtration plant would soon be paid back, apart from the ability of the properly-equipped bath to accommodate extra bathers. Harrow had had an increase of over 25 per cent. of visitors after the plant was installed. To these safeguards of construction Mr. Wilkinson added those of regular bacteriological inspection, the proper washing and disinfection of towels and suits, and hygienic education of all bathers. Instructors should give lectures from time to time on the use of the bath, showers, and the preliminary wash. There should be a suction-sweeper for the bottom of the bath.

However ideal such an installation may be, its practicability for all swimming baths may arouse discussion. Dr. L. R. Lempriѐre held that for public schools the cost would be prohibitive, whereas Dr. E. H. Nash maintained that expenditure so closely involving the health of children ought not to be called in question by school authorities. If purchased outside, the electrolytic fluid would cost perhaps £20 for the season for a school bath of 250,000 gallons, whilst even cheaper is nightly sprinkling of the surface with chloros fluid. Changing the water in such a bath costs £7 and takes three days each time out of the short swimming season. Copper sulphate and ultra-violet rays as disinfectants are not satisfactory, according to Dr. Forbes, and the merits of any simple form of disinfection have to be weighed against those of more complicated and expensive plants. It is certainly time that public school authorities followed public bodies in considering carefully the evidence for and against the dangers of untreated swimming baths.

TROPICAL DISEASES IN THE LIGHT OF HISTORY

THE current number of the *Tropical Diseases Bulletin* contains a section dealing with the historical aspects of tropical diseases. Records have been consulted from British, Portuguese, Dutch, French, American, Italian, and German sources, and a vast amount of varied and interesting information is presented, including descriptions of disease by the early Portuguese navigators and colonists, and the earliest notices of plague, malaria, leprosy, and scurvy. In a paper on the Portuguese of the Renaissance, read at Coimbra in 1925, Carlos França clearly showed that the missionaries and explorers of the fifteenth and sixteenth centuries were not concerned alone with souls and commerce, but had an astonishing flair for recognising diseased conditions and for describing them. Thus João dos Santos, a Dominican missionary, who visited East Africa in 1586, has left us a description of night-blindness, a complaint regarded as peculiar to Mozambique, Duarte Lopes noted the guinea-worm, while other observers describe the chigger flea, various myiases, cholera, snake poisoning, syphilis, and yaws. Other papers referred to in the *Bulletin* which will repay reading in the original are by Colonel W. P. MacArthur, "Old-Time Plague in Britain," by Prof. Ichok, "La peste dans le passe et a notre epoque," and by F. E. C. Coudray, "La peste a l'armee d'Orient de la 1re Republique." This excursion into tropical history leads us to hope that some learned member of the Bureau will look into the list of poisonous snakes and other animals of the Libyan deserts as given by Lucan in Book IX. of the Pharsalia (ll. 519 et seq.) where the effects of their bites are discussed with a vivid wealth of singularly unpleasant detail. Light might also be thrown upon the vexed question as to whether the Salpuga or Solfuga was a scorpion or a spider. We hope that this innovation will develop into a permanent feature of the *Bulletin*.

THE CENTENARY OF THE DISCOVERY OF BRIGHT'S DISEASE

A LUNCHEON will be held in the Governors' Court Room of Guy's Hospital on Friday, July 8th, to celebrate the centenary of the discovery of Bright's disease by Dr. Richard Bright, who was physician to Guy's Hospital from 1820 to 1843. The Earl of Balfour will be present, and subsequent to the lunch the Bright Memorial Oration will be delivered by Dr. W. S. Thayer, Emeritus Professor of Medicine, Johns Hopkins University, Baltimore.

---

[1] THE LANCET, 1926, i, 357.

It may be recalled that in THE LANCET of Oct 10th, 1925, Sir William Hale-White, in an interesting summary of Bright's life and work, gave the date from which the centenary should be counted as Oct 12th 1825, and the discrepancy may seem to require explanation, though it is contained in Sir William Hale-White's words He is dating the centenary from the commencement of Bright's investigations which were definitely started by an observation of the symptoms manifested in an intemperate sailor admitted into Guy's on Oct 12th, 1825 It was of this case that Bright said, after noting the "kidneys granulated throughout," the large heart, and the ascites, that in his opinion "the disease of the kidneys was the first established" His renowned "Reports of Medical Cases selected with a view of Illustrating the Symptoms and Cure of Diseases by a reference to Morbid Anatomy" appeared in two volumes, the first in 1827 the second in 1830, so that 1825 was the year when Bright began the study of the syndrome for ever associated with his name, and 1827, the year when his splendid observations, transformed from theory into fact, were ready for general publication

DENTAL BOARD PROBLEMS

IN his address from the chair at the opening of the twelfth session of the Dental Board of the United Kingdom Sir Francis Acland noted with satisfaction how few were the allegations of offence against a profession which had more than 14,000 names on its register What had, however, been giving the Board serious thought was the question of dental clinics in relation to advertising and canvassing A firm or organisation with a genuine desire to benefit its staff or members, and without any financial interest in the arrangement, may provide a dentist with a consulting-room or a surgery, on or off their premises, and may, or may not also pay him a fee. His work for them may be part-time only, but attendance upon their staff will give him an introduction to practice with the families and friends of those who come as patients The firm or organisation may call the attention of their staff or members to the fact that those who need attention to their teeth can attend, or are advised to attend, their clinic. giving the name of the dentist in attendance There can be no doubt, said Sir Francis Acland that this sort of thing is not at all popular in the profession It is for the fortunate individual a short cut to practice which is regarded as unfair to others who have no chance of being provided with patients ready-made But the question which the Board may have to decide does not turn on popularity, it is whether the dentist concerned has been guilty of "infamous or disgraceful conduct in a professional respect," or. to use the exact words of the notice on advertising and canvassing has adopted a practice "contrary to the public interest and discreditable to the profession of dentistry" It may be assumed (quoting from this notice) that he has not "acquiesced in the publication of any notice directing attention to his professional skill knowledge service or qualifications, or depreciating those of others," for the announcement of the clinic contains no such element Has he then adopted the practice "of advertising, whether directly or indirectly. for the purpose of obtaining patients or promoting his own professional advantage"? He has not done so directly The question is, "Has he advertised indirectly?" Having brought the question so far Sir Francis Acland said that it could only be rightly answered on a particular case and in view of the circumstances of it Another class of case that in which an approved society under the Health Insurance Acts says to a member who is entitled to treatment under their scheme "This is our dentist or these few persons are our dentists you must go to him, or to one of them if you require treatment" involves denial of free choice If a dentist knew that this practice was being adopted in connexion with him and permitted it he would be liable therefore to disciplinary action by the Dental Board

Turning to the financial assistance of likely pupils for the dental profession Sir Francis Acland corrected a mistake made by Colonel Wedgwood when speaking in Parliament on a Bill for the registration of architects He then said that since dentistry had been made a closed profession it had been made impossible to anyone to qualify unless he was able to lay out £1000 on the training "No misconception," he said 'could be greater The fold may be closed except through the proper entrance, but in no profession is the entrance so wide open for those who seem likely to be able to take advantage of the training, regardless of their means This fact ought to be widely known, and we shall have to consider means of making it even better known than it is to head masters of schools and others, who are likely to be in contact with those who may, with the assistance of our bursaries become well-qualified practitioners" The Educational Grants Committee in their report to the Board stated that of the 75 candidates for bursaries during the last 12 months 60 were accepted Deans of dental schools find that the Board's bursars compare favourably with the ordinary student in regard to all essential respects One dean remarks that he is tempted to think it might be an advantage if all students came in in the same way Of the 207 students who so far have been awarded bursaries, 40 (38 men and 2 women) have qualified

ANTENATAL TEACHING IN THE MEDICAL SCHOOLS

THE importance of directing the attention of medical students throughout their hospital career to the preventive aspects of medicine is emphasised by the General Medical Council in an additional resolution to the instructions issued with regard to professional education in medicine The Maternity and Child Welfare Group of the Society of Medical Officers of Health is alive to the need for exciting interest among students in the welfare of prospective mothers and infants, and has sought to ascertain by means of a questionnaire addressed to medical schools and qualifying bodies what steps are being taken to comply with the ruling of the General Medical Council that students must obtain instruction and pass an examination in antenatal conditions and infant hygiene From replies received the gratifying conclusion is drawn that the majority of the schools are fully alive to the value and importance of these branches of preventive teaching and have made arrangements for instruction of students in advance of the requirements imposed on them for examination The Maternity and Child Welfare Group note, however that the term 'infant hygiene" as used by the G M C is subject to a variety of interpretations. and desire to state that, in their opinion. infant hygiene should include the study of the normal child up to the age of 5 years The replies from the medical schools imply that for the most part the term is understood to mean the hygiene of the child beyond the age of 1 month and that the student may thus receive minimal instruction if any, in the management of the child beyond puerperium The existing arrangements in some schools for the clinical initiation of students into these particular subjects seem to the inquirers to be defective For the interest and information of those universities which have not yet made specific arrangements for clinical instruction of students in antenatal conditions and infant hygiene the Committee have set out in full two comprehensive schemes which are already in operation at St Thomas's Hospital and the London (R F H) School of Medicine for Women respectively The scheme at St Thomas's Hospital was set out recently by Dr John Fairbairn in an address to the Glasgow Obstetrical Society and is evidently one which could be adopted with advantage elsewhere The clinical teaching of obstetrics gynæcology, and pædiatrics extends over a period of six consecutive months

The first month is devoted to the study of the pregnant woman in the antenatal clinic and to the infant welfare clinics, the student thus obtains a view of the whole system of prevention early in his term For a month he is drilled in the maternity ward (600 deliveries per annum), and then for a month goes out in the district The next two months of his term are devoted to the study of the diseases of women in out-patient and in-patient departments, where the results of the injuries and infections of child-bed are seen In his final two months he returns to the infant welfare clinics, and attends both out- and in-patient departments for the diseases of children, where again he sees the effects of failure of prevention, and continues his gynæcological practice by attendance on two afternoons a week in the out-patient department for diseases of women Each hospital and medical school has its own special difficulties to overcome in cramming the curriculum into five or six brief years, but the scheme outlined appears to succeed in securing a more logical sequence of teaching than many of us were privileged to secure It may be that in the future the student will be enabled to view his course in a better perspective in all its branches For the more haphazard system or lack of system in the past it can only be said that the sorting out and rearranging of miscellaneous and apparently unconnected facts was a valuable foretaste of the conditions in which medical practice would have to be carried on by the student when qualified

---

The Royal Institute of Public Health is holding its annual congress at Ghent from Wednesday, June 1st, to Monday, the 6th The President will be Lord Burnham, and there will be five sections, devoted to State Medicine and Municipal Hygiene, Naval, Military, Air and Tropical Diseases, Industrial Hygiene, Pathology, Bacteriology and Biochemistry, and Women and the Public Health They will meet under the presidency, respectively, of Sir Alfred Mond, Air Vice-Marshal D Munro, Lord Leverhulme, Sir Berkeley Moynihan, and Lady Burnham The inaugural meeting, at 10 30 A M on Wednesday, is to be held in the Palais des Fêtes, when the King of the Belgians, accompanied by the Queen, will open the proceedings A reception at the Hotel de Ville is arranged for the same day, whilst other functions include a reception at the University, when honorary degrees will be conferred, a banquet, and a gala performance at the Royal French Theatre The Governor of Eastern Flanders will receive members of the congress at the Château de Beirvelde on Sunday afternoon, and in the morning Mass will be celebrated at the Cathedral of St Bavon The following day will be devoted to excursions in the neighbourhood

---

Next week 120 members of the Inter-State Post-Graduate Assembly of North America are to visit London and a series of lectures will be delivered on the mornings of June 1st, 2nd, and 3rd at Dartmouth House, the headquarters of the English-speaking Union, 37, Charles-street, W 1 The sessions will be opened at 10 15 A M on June 1st by Lord Reading and Lord Dawson of Penn In the afternoons a number of London hospitals have arranged to receive the guests, and on Thursday, June 2nd, at 5 30 P M, Sir Arthur Keith, F R S, will give a demonstration at the Royal College of Surgeons On the following day at 8 30 P M Sir James Berry (the President) and Lady Berry will receive members of the Assembly and ladies at the Royal Society of Medicine, where Dr G W C Kaye, of the National Physical Laboratory, will speak on X Rays and some of their Uses Lady Swaythling and other members of the English-speaking Union are to give a reception to the ladies at Dartmouth House on June 2nd, from 4 to 6 P M

Modern Technique in Treatment.

CCXXV.

THE TREATMENT OF INSECT BITES AND STINGS

Insect venoms may have one or several of the following effects (*a*) hæmolytic, (*b*) neurotoxic, (*c*) irritant—producing local inflammation, (*d*) producing profound and even fatal shock

Mosquitoes, Midges, and Flies

The nature and source of the poison introduced by a mosquito or gnat has been for long supposed to be the secretion of the salivary glands, but Nuttall and Shipley in 1903 and Schaudinn in 1904 showed that the evidence for this is far from conclusive. Nuttall and Shipley could find no evidence of hæmolysis or delayed coagulation produced by an emulsion of the salivary glands of *Culex pipiens* Schaudinn found that the irritation of a mosquito bite was due, not to the saliva, but to an enzyme contained in a commensal yeast which is a constant inhabitant of the œsophageal diverticula of the mosquito The yeast cells are injected into the wound by the insect when feeding, but are mostly sucked back again if the mosquito is allowed to finish its meal In the last year or two several deaths have been reported following mosquito bites which were apparently highly septic It seems likely that these results have been due to the mosquitoes having temporarily harboured virulent streptococci in addition to the normal yeast cells Horse-fly bites also are often highly septic, and cases are on record where anthrax has been inoculated by the bite of a horse-fly

Individual preventive measures against mosquito, midge, and fly bites consist in keeping the insects at a distance either by smoke from a fire or from tobacco, or by the application to the skin of some essential oil, such as that of citronella, which is a constituent of numerous proprietary articles designed for the purpose A useful prescription is—

℞ Ol cedri, ʒiss
Ol citronellæ, ʒiiss
Spt. camphoræ ad ℥i, misce.

This should be smeared on the skin of the exposed parts as often as is necessary. Cod-liver oil used in the same way has been highly recommended The irritation of a mosquito or fly bite may be allayed by gently rubbing the puncture with a moist cake of soap, or by applying a 1 per cent alcoholic solution of menthol, or 1–20 watery carbolic lotion Hydrogen peroxide or weak ammonia solution dabbed on are useful also If the bite shows any signs of being a septic one, it is important that measures should be taken at the earliest moment to combat the sepsis, either by constantly renewed hot boric fomentations or, if a limb is implicated, hot saline arm or leg baths, or Bier's treatment or antistreptococcal serum also may be advisable

Lice, Bugs, and Fleas

Methods for the destruction of lice, bugs, and fleas scarcely come within the scope of this article, but it may be mentioned that as a preventive against the bites of fleas the application to the skin of oil of pennyroyal, oil of birch tar (which has the not unpleasant smell of Russia leather), or oil of lavender, or the dusting of powdered pyrethrum, menthol, or camphor into the socks or underclothing are of service It should be remembered that fleas breed in cracks in floors and wainscots, that unoccupied fleas usually lie in wait on the floor, so that anti-flea preparations should be applied chiefly to one's legs or their coverings

The irritation of a flea-bite can be allayed by applications of 1–20 carbolic acid lotion or by the following ointments —

R
Ac carbol, ♏x
Menthol, gr v
Zinc oxide, ʒi
Adipem prep ad ℥i

or
Hyd ammon, gr x
Liq picis carb ʒi
Ung paraffin B P ad ℥i

Or by applying one drop of—

Ac carbol }Partes æquales
Spt vini meth

Some fortunate individuals appear to be naturally distasteful to fleas, and others possess, or acquire, a relative immunity to the effects of their bites The irritation caused by poison hairs of "woolly-bear" caterpillars may be allayed by bathing with a weak solution of ammonia or 1–20 carbolic lotion, or the application of moist sodium bicarbonate Castellani and Chalmers advise bathing with a 2 per cent sodium bicarbonate lotion followed by the application of a 10 per cent ichthyol ointment Kirkland (1907) advised that the following lotion should be well rubbed in —

R Ac carbol, gr xxx
Zinc ox, ʒiv
Aq calcis ad ℥viii
M ft lotio

Harvest Bugs

The familiar "harvest bugs," which are really the six-legged larval forms of various species of the acarid *Trombidium*, are normally parasitic on various insects, but readily attack man when he gives them the opportunity by walking through the grass or vegetation on which they are living

These larvæ are usually supposed to burrow into the human skin, or at least to penetrate the hair follicles, but Ewing in U S A. (1921), as a result of some careful observations on his own leg and ankle, found that this was not so The mites were from three to seven times too large to enter a sweat pore or hair follicle and were merely attached by their mouth parts, about 80 per cent on the smooth surface of the skin and 20 per cent at the bases of hairs with their mouth parts thrust down the hair follicles The characteristic burning sensation began in a few hours and increased for 36 hours

Protection from the attacks of these larval mites can be obtained by sprinkling flowers of sulphur or powdered naphthaline into the stockings and underclothes from the knee downwards The mites can be removed by mopping the skin with benzine or petrol or taking a warm salt bath, and the itching can be allayed by one of the ointments suggested for flea bites

Bees, Wasps, and Hornets

The sting of a bee, wasp, or hornet is always painful and may be dangerous Danger may arise on account of the situation of the sting—e g, in the tongue or fauces—when the great swelling which ensues in these regions may obstruct respiration and cause death from suffocation Such accidents are apt to happen to those who devour fruit without inspection sufficient to detect a concealed wasp

It is often stated that the serious symptoms of collapse and even death which occasionally follow a bee or wasp sting in a healthy person are due to the sting having penetrated a vein so that the venom is injected directly into the circulation This may sometimes be the case Another explanation may be that occasionally patients become anaphylactic to bee or wasp venom, and certainly some of the cases described have shown symptoms which might be explained as profound anaphylactic shock. It may be possible also that the venom of individual insects may, under certain conditions, be of exception potency

The sting of the bee and wasp is complicated, but its working is entirely reflex, so that it is easy to get a severe sting from a bee s abdomen which has been for many hours separated from its thorax The poison sac and glands are usually left behind by the bee attached to the sting The poison forming apparatus consists of a long acid-forming gland and a much smaller alkali forming one A detailed study of the poison of some 25,000 bees was published by Joseph Langer in 1897. He found it to consist of formic acid plus an organic base The pure poison placed on uninjured skin produced absolutely no irritant effect, but caused a marked reaction on the mucous membrane of nose or eye The slightest break in the skin surface, or a needle puncture through a drop of the poison caused typical effects—i e, local necrosis surrounded by hyperæmia, œdema, and infiltration of leucocytes Further studies on bee poison were published by F Flury in 1920 He had investigated the poison from some hundred thousand bees and found that apart from the formic acid a considerable portion seemed to be lipoid in character By hydrolysis he was able to split off cholin, glycerol, phosphoric acid, palmitic and other fatty acids, an indol derivative, presumably tryptophane, and an unidentified non-nitrogenous component The latter he believed to be the active component of bee poison It produced hæmolysis and behaved like the hæmolytic saponins Flury regards bee poison as a complex of lecithin with basic components, showing resemblances on the one hand to the protein-free sapotoxins, and on the other to poisons of the cantharidin type Some snake venoms include saponin-like poisons (krotalotoxin and ophiotoxin) which account for their hæmolytic properties The potency of cantharidin as an irritant poison explains the local inflammatory reaction resulting from a bee sting

Treatment of a bee or wasp sting consists, first of all, in removing the sting This should *not* be laid hold of with forceps or fingers and pulled out Such a proceeding will squeeze the poison sac and force more poison into the wound The sting should be lifted or scraped out with the blade of a knife or the edge of a long finger-nail The application usually recommended is solution of ammonia It is important that this should be dabbed on and not rubbed, or it will rapidly remove the epidermis In the absence of ammonia, gentle rubbing with a moist cake of soap may be tried The application of a bag of washing blue is a household remedy of great popularity Hot fomentations are useful in relieving the pain of severe stings While the poison of the bee is acid, it was pointed out by E R Speyer in 1919 that that of the wasp is alkaline and that therefore in the case of wasp stings an acid application, such as vinegar, should be more effective in relieving the pain than an alkali

J F D Donnelly (1898) recommended ⅙ gr of cocaine dissolved in a few drops of water and rubbed on the puncture with the finger He found that this almost removed the pain, and a second application 1–2 hours later completed the cure One would expect hypodermic injections to be even more effective Pugnat (1918) found that the immediate local application of a saturated solution of aloes in alcohol was of material benefit in treatment of wasp stings and insect bites He found that if the solution were rubbed in immediately no local or general reaction took place Langer, in his experimental studies, found that bee poison was very rapidly destroyed by pepsin, but I can find no record of this preparation having been used clinically

The treatment of cases where sudden collapse follows the sting of a bee must be on the usual lines for the treatment of shock and collapse

MEDICINE AND THE LAW.

Allegation of Mistaken Diagnosis: Medical Officer of Health's Successful Libel Action.

DURING the small-pox epidemic at Southport last January a Liverpool evening newspaper published some unfortunate paragraphs which suggested that cases of chicken-pox were being diagnosed as small-pox. One such statement was headed "Not Small-pox after all —Some Southport Cases Breathe Again." The statements were totally untrue. All the cases sent to the isolation hospital at the date when these paragraphs appeared were cases of small-pox and were retained at the hospital as such, and in no instance was a case of chicken-pox diagnosed as small-pox. These misstatements were obviously unhelpful to the medical officer of health who was contending with the epidemic. It is notoriously difficult to persuade some parents to let their children be sent off to an isolation hospital, and, if a responsible newspaper suggests that wrong diagnoses are being made and that sufferers from chicken-pox are being exposed to small-pox infection in hospital, the task is certainly not made easier. Moreover, the misstatements were also a serious libel upon the medical officer of health both in his capacity as an official and in his capacity as a medical practitioner. In these circumstances an action was begun against the printers and publishers of the newspaper by Dr. G. C. Barnes, the medical officer of health for Southport, and Dr. W. E. Fitzgerald, the deputy medical officer. The case came on before Mr. Justice Roche at the Liverpool Assizes early in the present month, and the newspaper (which had already published an apology) very frankly stated that it had found its statements to be incorrect and very handsomely expressed its regret. Judgment was entered for the plaintiffs on agreed terms, the defendants paying the nominal sum of £100 damages and undertaking to pay the plaintiffs' full costs as between solicitor and client. It was explained that Dr. Barnes and Dr. Fitzgerald, though they had suffered considerable damage and annoyance, did not desire to make any pecuniary profit out of the proceedings which they had felt themselves compelled to institute, and it was intimated that they would hand over to some charitable institution the sum received by way of damages.

Doctor's Libel Action against Solicitor: Privilege Exceeded.

Later in the month a doctor was successful as plaintiff in another libel action—this time in the High Court in Dublin. Mr. Justice Hanna's judgment, which outlined the facts, showed that Dr. Henry McKeogh, of Portroe, Killaloe, Co. Clare, medical officer of health of Portroe, had had occasion to complain of a nurse who acted as midwife in the district. After various complaints Dr. McKeogh refused to attend cases with her; he complained informally about her to the medical inspector of the Department of Local Government and Public Health, and finally, after a further case of puerperal fever had occurred, he reported formally to the department. That report formed, it appears, the ground of a separate libel action by the nurse against Dr. McKeogh; it also led to the proceedings in which the latter was plaintiff. The nurse went to a solicitor in Limerick, who wrote on her behalf to the Limerick County Council. The object of the letter was the entirely proper purpose of putting forward the nurse's reply to the complaint against her. The letter, however, went beyond mere defence. It contained the following sentence: "She will be able to prove when the time comes that there was greater reason for complaint against Dr. McKeogh in the treatment of his patients than there was against her." This being a damaging statement reflecting upon his professional skill and care, Dr. McKeogh thereupon brought a libel action against the solicitor. The judge found that the statement was without foundation. Indeed no attempt was made to justify it, the defendant relying upon the supposed immunity of a lawyer's letter. Mr. Justice Hanna rejected this defence. Words spoken in court, he said, by an advocate (whether solicitor or counsel) are absolutely privileged even if something defamatory is uttered with actual and deliberate malice. But a solicitor writing to third parties is in no better position than his client. He is not free to write anything his client may suggest. He must not allow himself to be the conduit-pipe for every defamatory allegation of a chagrined or malignant litigant. The statement inserted in the letter relating to Dr. McKeogh was intended as a countercharge and was not relevant to the occasion. It went beyond the reasonable limits of self-defence. Though the letter was otherwise written upon a privileged occasion and there was no evidence of express malice, the passage which attacked Dr. McKeogh was outside the privilege and was untrue in fact. The court awarded the plaintiff £25 damages.

NOTES FROM INDIA.

The Calcutta Congress.

MEDICAL men in Calcutta are displaying considerable enthusiasm at the prospect of having the seventh session of the Congress of the Far Eastern Association of Tropical Medicine in Calcutta in December next.[1] Preliminary arrangements on an elaborate scale are already in hand, and it is understood that a full-time officer of the Indian Medical Service will be appointed soon to have charge of the arrangements. A sub-committee has already been formed to carry on a publicity campaign. Four classes of delegates and members will attend the Congress—viz., official foreign delegates, estimated at 70; non-official foreign members, estimated at 50; official delegates from the local and Indian Governments and Indian States, numbering about 50, and private members from India numbering about 350.

A Lecture on the Congress.

In anticipation of the Congress to be held in December, Lieut.-Colonel A. D. Stewart recently delivered an interesting address at the Calcutta Rotary Club on Internationalism in Public Health; his object being to draw attention to the importance of the Congress and its influence and activities. He began by stating that the public health of a nation ultimately depends on the knowledge of health matters possessed by the individual, on the way in which he applies this knowledge, and on the amount of money which he is willing to pay in support of his conviction. He also pointed out that attention has been focused upon India as the possible storehouse and distributor of cholera, plague, and small-pox in the East, and indeed throughout the world. In the past 20 years plague killed 10½ million people in India, and influenza, which appeared in 1919, destroyed about 8½ million lives within two years. The average span of life in India is 25 years instead of 50 as it is in more fortunate countries. Colonel Stewart ended by referring to the importance of controlling disease internationally and by describing the present organisations for this purpose.

Indian Medical Service.

According to new rules issued by the Government of India, all officers appointed in India to the Indian Medical Service are to be sent to England within the first year of their service to take the junior Royal Army Medical Corps course. All officers of the I.M.S., including those of Asiatic domicile, will also be required before promotion to the rank of Major and between the seventh and tenth years of their service to complete the senior medical college course,

---

[1] See THE LANCET, May 7th, p. 1007.

Millbank. Attendance at both these courses will be regarded as duty and will carry with it free passage to and from the United Kingdom. Officers of the I.M.S. of Asiatic domicile, whether in military or civil employ, will be allowed a period of study leave immediately after completing the senior officer's course at Millbank.

The present strength of the I.M.S. is: permanent officers, 495 European and 152 Indian; temporary officers, 5 European and 130 Indian.

Ranchi Radium Institute

The Radium Institute at Ranchi is the only institution in India where there is a good supply of radium. In his report for the past year, Major H. K. Rowntree, I.M.S., superintendent of the institute, points out that it is impossible for patients to come from all parts of India to Ranchi and therefore, if India is not to lag behind the rest of the world in its treatment of cancer, it is incumbent upon local governments to make provision for treatment by radium or radium emanation in a large centre in each province. Major Rowntree points out further that many cases are sent up for treatment as a forlorn hope when every other treatment has failed. The number of new cases treated during the year was 247. There is no steady annual increase in the number of patients, which he attributes to the fact that the existence of this institute is not well known either to the public or to the medical profession. It is also found that a number of patients abandon treatment for financial reasons; it is difficult for the common ryot to support himself and his sick attendant at Ranchi where the cost of living is comparatively high, and after one application of radium the majority of patients run away to their homes.

The International Convention

At the International Sanitary Convention of 1926[1] India was for the first time represented by a separate delegation, but approval of the draft proposals is not unqualified here. Commenting on its recommendations the Bengal Chamber of Commerce criticises the decision to put upon shipowners the cost of measures of surveillance that may arise from conditions of health in their countries. Although ratification of the Convention would not, in fact, greatly increase the charges upon shipowners, it would involve the ports in heavy expenditure and the Chamber maintains that this burden should fairly be borne by the general revenues of the country. The Chamber also objects to Part III of the Convention's proposals—which deals with arrangements for pilgrim traffic—on the ground that for 30 years India has enforced sanitary regulations which have proved effectual and it would be a mistake to supersede them. In general the Chamber thinks that the draft Convention should be considerably modified before being ratified by the Government of India.

The Cholera Epidemic

Cholera is raging in Bengal and in the southern part of the Bombay Presidency; during the last quarter of 1926 15,000 deaths were reported. In February there was a decline, but since March the epidemic has taken a turn for the worse, and in many villages the population is said to have been decimated. The position in Calcutta is also disquieting, and Government are taking energetic steps to prevent the spread of the disease.

The last quarterly report of the medical officer of health for Bombay municipality states that the number of deaths from all causes was 7300, which was less by 4781 than the mean for the first quarter during the previous ten years.

During 1926, it is reported, there were 704 deaths from snakebite in the Punjab. This is about 12 per cent. less than in the previous year, and the reduction in mortality fully justifies the measures employed for the destruction of snakes.

IRELAND

(From our own Correspondent.)

The Medical Practitioners Bill

This Bill passed through the Senate unchanged last week, and may by now have received the Governor-General's consent. It does not come into force, however, until legislative authority has been given at Westminster to the international agreement on which it is based. The satisfactory solution of a problem which at one time gave rise to almost unbounded alarm is no small tribute to the ingenuity and patience of the Ministers concerned.

Medicine and the General Election

It is a matter of much regret to the entire medical profession in the Irish Free State that Mr. T. Hennessy, F.R.C.S.I., one of the deputies for the South Division of Dublin City, has decided not to seek re-election to the Dail. He has found that his health was likely to be adversely affected by the strain his duties entailed. His retirement from the Dail is a real public loss. He had the respect and affection of members of all parties, and his deep interest in and knowledge of matters concerning health gave him a right to speak with authority. Most of the other medical men who are on the Dail are seeking re-election. Sir James Craig, one of the three members for Dublin University, in common with his colleagues has to stand a contest, an outside candidate having appeared in the field. There are contests also in South Dublin and in Waterford, where Mr. Myles Keogh and Mr. Vincent White are respectively candidates.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH

County Borough of Bootle

Statistics for 1926.—Population, 84,580. Birth-rate, 22.0. Death-rates per 1000 of the population: All causes, 11.9; tuberculosis, 1.17; cancer, 1.12; respiratory diseases with influenza, 2.5; heart disease, 0.7. Death-rates per 1000 births: neonatal, 39; infant, 100; maternal from childbirth, 1.1.

Dr. F. T. H. Wood shows that the guardians gave more indoor and outdoor relief during 1926 than in 1925, but that the monthly averages of adult males, women and juveniles on the unemployed registers were less. Steps are being taken to secure amendments of local Acts in order to facilitate the substitution of portable bins for fixed ashpits. At the end of 1926 there were about 8000 houses in need of this improvement. Since the close of the year a new refuse disposal plant, combining salvage and incineration, has been put into operation. The cost of construction was about £22,500. The dust is separated by screening for manure; the remainder is sorted by hand and by magnetic drums as it passes on to the furnaces by a revolving belt, and the furnace clinker is used for making paving, concrete, and mortar.

Progress is being made in enforcing the provisions of the new milk order, which have been operative since Oct. 1st, but in some cases the small yard space makes it difficult to provide a cooling shed outside the cowhouse. The number of cows kept in the borough has decreased to 360 from the pre-war figure of 550. Dr. Wood records an improvement in the cleanliness of the local milk-supply, judging by its bacterial content. Of 28 samples examined 7 reached the standard of "Certified" milk and 5 of "Grade A" milk, but 9 were "grossly contaminated." Two of the samples contained tubercle bacilli.

No small-pox occurred in Bootle but its presence in the country evidently stimulated vaccination, as there were 1671 successfully vaccinated infants as compared with 1149 in the previous year. This marks a return to the experience of a few years ago, when 90 per cent. of the infants received protection. Infantile diarrhœa

DURING the small-pox epidemic at Southport last January a Liverpool evening newspaper published some unfortunate paragraphs which suggested that cases of chicken-pox were being diagnosed as small-pox One such statement was headed "Not Small-pox after all —Some Southport Cases Breathe Again" The statements were totally untrue All the cases sent to the isolation hospital at the date when these paragraphs appeared were cases of small-pox and were retained at the hospital as such, and in no instance was a case of chicken-pox diagnosed as small-pox These misstatements were obviously unhelpful to the medical officer of health who was contending with the epidemic It is notoriously difficult to persuade some parents to let their children be sent off to an isolation hospital, and, if a responsible newspaper suggests that wrong diagnoses are being made and that sufferers from chicken-pox are being exposed to small-pox infection in hospital, the task is certainly not made easier Moreover, the misstatements were also a serious libel upon the medical officer of health both in his capacity as an official and in his capacity as a medical practitioner In these circumstances an action was begun against the printers and publishers of the newspaper by Dr G C Barnes, the medical officer of health for Southport, and Dr W E Fitzgerald, the deputy medical officer The case came on before Mr Justice Roche at the Liverpool Assizes early in the present month, and the newspaper (which had already published an apology) very frankly stated that it had found its statements to be incorrect and very handsomely expressed its regret Judgment was entered for the plaintiffs on agreed terms, the defendants paying the nominal sum of £100 damages and undertaking to pay the plaintiffs' full costs as between solicitor and client It was explained that Dr Barnes and Dr Fitzgerald, though they had suffered considerable damage and annoyance, did not desire to make any pecuniary profit out of the proceedings which they had felt themselves compelled to institute, and it was intimated that they would hand over to some charitable institution the sum received by way of damages

Doctor's Libel Action against Solicitor Privilege Exceeded

Later in the month a doctor was successful as plaintiff in another libel action—this time in the High Court in Dublin Mr Justice Hanna's judgment, which outlined the facts, showed that Dr Henry McKeogh, of Portroe Killaloe, Co Clare, medical officer of health of Portroe, had had occasion to complain of a nurse who acted as midwife in the district After various complaints Dr McKeogh refused to attend cases with her, he complained informally about her to the medical inspector of the Department of Local Government and Public Health, and finally, after a further case of puerperal fever had occurred, he reported formally to the department That report formed, it appears, the ground of a separate libel action by the nurse against Dr McKeogh; it also led to the proceedings in which the latter was plaintiff The nurse went to a solicitor in Limerick, who wrote on her behalf to the Limerick County Council The object of the letter was the entirely proper purpose of putting forward the nurse's reply to the complaint against her The letter, however, went beyond mere defence It contained the following sentence "She will be able to prove when the time comes that there was greater reason for complaint against Dr McKeogh in the treatment of his patients than there was against her" This being a damaging statement reflecting upon his professional skill and care, Dr McKeogh thereupon brought a libel action against the solicitor The judge found that the statement was without foundation Indeed no attempt was made to justify it, the defendant relying upon the supposed immunity of a lawyer's letter Mr. Justice Hanna rejected this defence Words spoken in court, he said, by an advocate (whether solicitor or counsel) are absolutely privileged even if something defamatory is uttered with actual and deliberate malice But a solicitor writing to third parties is in no better position than his client. He is not free to write anything his client may suggest He must not allow himself to be the conduit-pipe for every defamatory allegation of a chagrined or malignant litigant The statement inserted in the letter relating to Dr McKeogh was intended as a countercharge and was not relevant to the occasion It went beyond the reasonable limits of self-defence Though the letter was otherwise written upon a privileged occasion and there was no evidence of express malice the passage which attacked Dr McKeogh was outside the privilege and was untrue in fact The court awarded the plaintiff £25 damages

NOTES FROM INDIA

The Calcutta Congress

MEDICAL men in Calcutta are displaying considerable enthusiasm at the prospect of having the seventh session of the Congress of the Far Eastern Association of Tropical Medicine in Calcutta in December next[1] Preliminary arrangements on an elaborate scale are already in hand, and it is understood that a full-time officer of the Indian Medical Service will be appointed soon to have charge of the arrangements A sub-committee has already been formed to carry on a publicity campaign. Four classes of delegates and members will attend the Congress—viz , official foreign delegates, estimated at 70; non-official foreign members, estimated at 50, official delegates from the local and Indian Governments and Indian States. numbering about 50, and private members from India numbering about 350

A Lecture on the Congress

In anticipation of the Congress to be held in December, Lieut -Colonel A D Stewart recently delivered an interesting address at the Calcutta Rotary Club on Internationalism in Public Health his object being to draw attention to the importance of the Congress and its influence and activities He began by stating that the public health of a nation ultimately depends on the knowledge of health matters possessed by the individual, on the way in which he applies this knowledge, and on the amount of money which he is willing to pay in support of his conviction He also pointed out that attention has been focused upon India as the possible storehouse and distributor of cholera, plague, and small-pox in the East, and indeed throughout the world In the past 20 years plague killed 10½ million people in India, and influenza, which appeared in 1919. destroyed about 8½ million lives within two years The average span of life in India is 25 years instead of 50 as it is in more fortunate countries Colonel Stewart ended by referring to the importance of controlling disease internationally and by describing the present organisations for this purpose

Indian Medical Service

According to new rules issued by the Government of India, all officers appointed in India to the Indian Medical Service are to be sent to England within the first year of their service to take the junior Royal Army Medical Corps course All officers of the I M S., including those of Asiatic domicile will also be required before promotion to the rank of Major and between the seventh and tenth years of their service to complete the senior medical college course.

[1] See THE LANCET, May 7th, p 1007

justified the appointment of an inspector during the busy season to ensure that the Act relating to employed children is enforced

West Bromwich C B

The year 1926 was apparently not an easy one for the medical department A temporary assistant was employed to complete the medical inspection in the schools, and pressure of work no doubt accounts for the somewhat meagre information given in the report by Dr A B Hamilton, the deputy school medical officer It contains little besides the statistical details required by the Board. Records from the maternity and child welfare centre are obtained, but no system of automatic transfer to the school medical department is in operation A survey of all cripples attending school showed that out of 76, 47 had had complete or partial treatment and 29 had had none There is no orthopædic scheme, although the authority defrays the whole or part of the cost in necessitous cases attending the orthopædic hospital Minor postural defects are treated by remedial exercises at the clinic, and breathing exercises are taught to children after their tonsils and adenoids have been removed There are no open-air schools or school baths, and no provision is made for blind, deaf, epileptic, and mentally or physically defective children An experiment to demonstrate the properties of vitaglass was started in Greets Green infants' department

Dumfriesshire

Dr John Ritchie, the S M O , says that there is much room for improvement in the hygiene of the schools The statistical details required in Scotland are not the same as in England and Wales, and thus, together with a different method of recording defects, largely accounts for the small proportion of defects found For instance, pediculosis is recorded in 0 18 per cent of children, but this only refers to those on whom lice were discovered " in considerable numbers," and the incidence of impetigo is given separately for the head and body The personal factor in all estimates of general condition makes individual comparison almost impossible Dr Ritchie records the nutrition of Dumfriesshire children as: " Above the average," 43 03 per cent , " average," 27 09 per cent , and " below average," 29 76 per cent but it is not stated whether any formula or figures of weight and height were used as a standard, or whether the estimate is purely clinical, and it can hardly be assumed that so large a percentage of the children are of first-class nutrition Dr. J. F Davidson compares the heights and weights of children examined between 1911–15 with those of children seen between 1919 and 1924, and concludes that post-war children compare favourably with the pre-war in nearly every age-group Very detailed statistical tables are given, showing the percentage of defects in boys and girls, of all the major and minor defects found during the medical examinations An immense amount of work is here represented, the value of which is doubtful The annual report offers a great opportunity of interesting the parents and the layman and, by drawing conclusions from the conditions found, of showing the way to health To record the findings statistically is not enough.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 14TH 1927

Notifications —The following cases of infectious disease were notified during the week —Small-pox, 271 (last week 337) scarlet fever 1411 . diphtheria, 838 enteric fever, 75 , pneumonia 973 , puerperal fever, 41 ; puerperal pyrexia, 127 , cerebro-spinal fever 13 · acute poliomyelitis 6 · acute polio-encephalitis 2 , encephalitis lethargica, 25 , continued fever, 1 , dysentery, 9 , ophthalmia neonatorum, 123

Cases of small-pox were notified from the counties of London 2 (Hampstead and Poplar), Derby 4, Durham 102, Lancaster 4, Lincoln Lindsey 1 (Spilsby), Northumberland 17, Warwick 2 (Coventry and Nuneaton), Yorks North Riding 1, West Riding 65, Monmouth 73 The last of the quarantine cases has been discharged from Hendon (Middlesex)

Deaths —In the aggregate of great towns, including London, there were 1 (1) deaths from small-pox, none from enteric fever, 57 (0) from measles, 5 (0) from scarlet fever 24 (8) from whooping-cough, 30 (3) from diphtheria, 59 (13) from diarrhœa and enteritis under 2 years, and 47 (8) from influenza The figures in parentheses are those for London itself, where the small-pox death was registered from Hampstead

The Case of Typhus Fever in Sunderland

We are indebted to Dr E Thorp temporary M O H of the county borough of Sunderland, for the following notes on the case of typhus fever notified in the Registrar-General's weekly return No 18, 1927, as having occurred in Sunderland Port Sanitary District

The port sanitary inspectors had visited the s s *Capitaine Henri Rallier* on April 28th, the day of its arrival in this port, when the captain reported " All well " The ship was revisited the following day, when the master reported that a seaman aged 19 years had been attended by Dr Ayre Smith, who ordered his removal to the Royal Infirmary, Sunderland, as suffering from pyrexia and pulmonary congestion In view of the doctor's report the case was treated as non-infectious The ship left Sunderland on April 30th and proceeded to Dieppe The patient at the Royal Infirmary was placed under the care of Dr J B Waters, who asked me to see the man I saw him on May 2nd, but came to no definite conclusion On May 3rd I had him removed to our isolation hospital as a suspicious case of typhus and on May 4th Dr W V Shaw, of the Ministry of Health, and myself were both of the opinion that it was a definite case of typhus fever

The history as given at the Royal Infirmary was of pain in chest of six days' duration, malaise fever, and a headache for the first three days No vomiting , bowels constipated , rash had appeared on body and limbs during the past few days On admission a faint purplish subcuticular rash not raised above surface was present on abdomen and chest, and more marked on thighs and legs—extensor aspect Faint staining on right arm and back—remains of rashes The mottling became more marked the next day On May 2nd the pathological report showed a negative Weil-Felix reaction and a negative Widal The urine continued bile, also blood

The patient had joined the ship at Havre and had only been 18 days on board when removed to the infirmary The louse found was pediculus pubis

---

BARBADOS GENERAL HOSPITAL —The report has been issued of a subcommittee of the Public Health Commission appointed to inquire into the system of administration of the General Hospital, Barbados The institution costs about £17,000 per annum, most of which is provided by the Colonial Treasury , there is accommodation for 220 patients , the average number of in-patients is 3566 and of out-patients and casualties 35,000 There are three resident surgeons, one of whom is on duty for 24 hours at a time, while the other two have what the committee think " must often be a burdensome amount of relaxation." The salary of the resident surgeon, which has not been increased for 30 years is insufficient to secure the filling of the post by men not only of good training, but with some experience of the working of a hospital The salary should be approximately £600 a year, with free quarters, and the committee make the carefully restrained comment that " the practice of appointing inexperienced men who very often have just graduated in medicine to be responsible for the administration and a certain amount of the medical work needs reconsideration " The standard of training for the nursing staff " seems to require improvement " There is no definite scheme of training, lectures by the resident surgeons are " given casually " and examinations " may be deferred indefinitely " Finally the committee find that " there is no work performed which is worth the name of pathological investigation," and they recommend that the bacteriologist should be responsible for all such work. The general death-rate of the hospital during the last five years was 7 8, including cases which died within 48 hours of admission The number of patients cured or improved is in accordance with the present standard of knowledge has been notifiable for some years during the third quarter During 1926 both notifications and deaths showed an increase and the death-rate from diarrhœa and enteritis under 2 years of age was double the English rate of 8 7 The use of the Schick test for scarlet fever admissions since 1924 shows that 50 out of 81 children under 5 years were positive, 55 out of 129 of the 5–10 age-group, 12 out of 54 of the 10–15 4 out of 15 of the 15–20, and only 1 out of 8 above the age of 20 Of four new probationer nurses one only was positive and had to be immunised

Referring to the high tuberculosis death-rate, Dr Wood points out that this excess occurs in neighbouring Merseyside areas and that the Bootle rate for the ten years ended in 1925 was 1 8 During 1926 two-thirds of the pulmonary deaths occurred between 20 and 55 years of age and two-thirds of the non-pulmonary under 15 years of age A light treatment clinic by general irradiation at Linacre Hospital, opened in October, 1925, has given satisfactory results, although its eccentric position interferes with regular attendance of the out-patients Some of the outstanding successes were a marasmic 3 months' old baby, a man with sacro-iliac disease and a sinus, and another man with tuberculous epididymitis and a sinus The year's results of the V D centre show that only 23 cases were discharged after completion of treatment and observation, whereas 69 ceased attendance before completion of treatment and 49 before final tests of cure

To the maternity home 16 cases were admitted for antenatal treatment and 167 for confinement There were no maternal deaths, eight stillbirths, and four deaths of infants within ten days of birth The average duration of stay was 14 1 days, and the cost worked out at £9 per case, of which £2 6 was contributed by the patients The neonatal mortality has been practically stationary in Bootle for 25 years There were 25 births of illegitimate infants and 10 deaths, equivalent to a rate of 400 The council have decided, in accordance with the Ministry's suggestion, not to attempt to recover the fees paid by them to medical practitioners called in to give aid in the case of discharge from the newly-born infants' eyes

Dr Wood, in discussing the housing shortage, shows that nearly 500 houses have been erected by the municipality during the last seven years and that this new housing provision " can be repeated without risk of overbuilding " The percentage of families sharing a house, which in 1901 and 1911 was 10 6, in 1921 was 13 6 , and in order to revert to the old standard 1371 new houses are needed

Borough of Stafford

1926 statistics —Population, 29,270 Birth-rate, 16 4 Death-rates per 1000 of the population All causes, 10 8, tuberculosis, 1 06 , cancer, 1 26 , respiratory diseases with influenza, 2 1 , heart disease, 1 8 Death-rates per 1000 births neonatal, 33 , infant, 60 , maternal from childbirth, 6 2

Dr J T MacNab reports that the progress of the new bio-aeration sewage disposal scheme has been delayed by difficulty in dealing with the spent liquor from the gasworks Experiments are being made with a view to reducing the amount of this liquor discharged into the sewers, and it is hoped that the difficulty has now been overcome

The water-supply has been carried to Dunston, four miles from Stafford, and the houses on the line connected up The new reinforced concrete service reservoir, to hold a million gallons, has been begun Six of eight private pumps at Doxey were found to yield polluted water and three of the houses have been connected to the mains The trouble with stoppages of waste-water closets continues There were 1374 stoppages among 2243 closets, and in 85 cases the trouble was caused by cans and scrubbing-brushes being dropped down the w c Uncovered wooden tubs for house refuse are being gradually replaced by iron bins

The town is fairly free from smoke except at the north end, where 22 stacks from the salt works emit smoke over a large area and cause a considerable nuisance There is said to be a difficulty in evaporating brine without causing smoke It is difficult to understand why Fish-frying has been declared an offensive trade Several new applications were refused on account of unsuitability of premises, and the public demand is said to be well met by the 24 fried-fish shops on the register The new houses erected numbered 156, more than in any other year since the war, about half municipal and half by private enterprise with subsidy Municipal houses only accommodate families catered for by the private builder before the war and do not touch the needs of the unskilled worker or casual labourer with a family of young children Dr MacNab does not favour flats, but advocates houses in rows or terraces at even more than 20 to the acre and the omission of the separate bath-room and hot-water cylinder and the substitution of a bath in the scullery with hot water run into it from a copper on a slightly higher level

The non-structural regulations of the Milk Order of 1926 came into force on Oct 1st, and a good deal of difficulty is being experienced in enforcing the clean milk provisions with respect to cleanliness of udders, milking-stools, &c , but some progress is being made, and the good results obtained in one or two cases are being put forward as examples and incentives to the laggards The 48 premises, on which ice-cream is made, were kept in a generally clean condition Stafford appears to have about one fried-fish shop and two ice-cream shops for 1000 of the population

The more severe cases of scarlet fever are being treated with antitoxin with encouraging results, and immunisation against diphtheria is offered through the welfare centre for children under school age Of the 29 infant deaths 17 were from congenital malformations and premature birth

‡ Numbers for which accommodation is provided

Margate

Dr Rowan McCombe shows that the attendance of children at the treatment clinic has not diminished under the scheme by which payment for treatment is collected from parents Payment is not pressed for, but is rather accepted as a voluntary contribution, and the total amount received has been satisfactory Delicate pre-school children attend the infant welfare centre and are examined by the school medical officer A feature of the Margate schools is the encouragement given to children to bring their midday meals and the arrangements made for warming the food The nature of the food and the method of taking it can be supervised, the long walks to and from home during the winter months are avoided, and the children are happy together Dr McCombe comments on the small amount of heart disease and the absence of rheumatism among the school population, giving as a reason the dry and bracing climate of Margate

Kent is badly in need of provision for mental defectives , it is almost impossible to get accommodation for this class of pupil A committee has been formed for the Isle of Thanet, and an occupation centre is to be started in Margate

Ninety-one children are employed in the district All are strong and healthy, and but few are working overtime, which satisfactory state of affairs has fully scores in the group tests or in the Binet test may prove to have low intelligence when examined by the Porteus tests, and many boys whose intelligence is low in the verbal tests frequently score high in the Porteus tests These exceptional cases are numerous and important Moreover the Porteus tests seem to furnish a reliable estimate of industrial capacity and of temperamental type They specially indicate such qualities of intelligence as ability to plan strength of inhibitions and carefulness of execution In addition to these advantages the Porteus tests yield a mental ages core in terms of practical social efficiency as opposed to the intellectual efficiency revealed by the Binet tests "

Considering Doll s experience as psychologist in the reformatories and jails of New Jersey his testimony must be regarded as having weight in this matter. It might be noted that I have never made any claims for the tests which go beyond this statement of Doll s

In conclusion, might I state once again what I have already in many publications given as my position in this matter I do not, and have never claimed that the maze tests are adequate measures of temperament, or moral character, or intelligence They do seem, however, to give some measure of certain important temperamental or social traits I have never advocated that they should be applied alone nor their single verdict relied upon except where other tests are clearly inapplicable They are by no means perfect instruments of diagnosis or research —the psychopathic frequently and the steady-going defective rarely, may slip through their meshes so that failure in the tests is always more significant than success They are not tests of planning capacity as such *but of the individual's tendency to use planning capacity in a simple situation* Unless practice effects are allowed for, they cannot safely be reapplied to the same children and hence their reliability cannot be tested by the ordinary reliability coefficient formulæ Taken by themselves, as measures of moral worth, they are decidedly inadequate I should as soon expect every criminal to fail in the tests as I should every insane person In other words I have no more faith in the maze tests than I have in tests in general, they merely represent one angle of approach to the problem of social and mental diagnosis and are not to be relied upon too implicitly. In short perhaps the best that can be said of the maze tests is that they are among the best of a poor lot However, until someone devises a better test for temperamental traits I shall continue to recommend their use One claim also I shall continue to make without fear of refutation—there is no performance test in use at present which has had so much work done on it in the way of proving the test itself and of providing data for its interpretation, nor has any other performance test been more widely or more variously employed.

The belief that I have made other claims for the tests may be due to the fact that I have consistently criticised the practice, at one time so common in America, of relying entirely for all purposes of mental diagnosis and prognosis on a Binet test alone This attitude has been twisted by some to mean that I believed that my test would do everything that was left undone by the Binet and that any examiner who was armed with a maze test and a Binet was thereby a clinical psychologist !

Might I add that Dr. Healy's work, and particularly his attitude to mental testing in general, is to my mind thoroughly admirable In clinical work I believe in the adequacy of his method and I use some of his tests P C II is a very valuable test, and will occupy a permanent place in clinical examinations It differs considerably in nature from the maze and as each has its value there is no need for drawing invidious comparisons between them

I am, Sir, yours faithfully,

S D PORTEUS,
Professor of Clinical Psychology, University of Hawaii
March 16th 1927

RADIOGRAPHY IN THE TREATMENT OF FRACTURES

To the Editor of THE LANCET

SIR —We are astonished to see in the columns of THE LANCET for last week a letter. under this heading, signed by Dr C Leonard Williams honorary secretary of the Todmorden Medical Society, referring to a circular letter issued by the Medical Defence Union to its members only. and which was for obvious reasons marked " private and confidential "

This circular letter was in the nature of friendly warning and advice to members of the Medical Defence Union from the Council based on its experience in a large number of recent cases It is obvious that this circular letter has been misinterpreted but public discussion of a matter of this sort in THE LANCET could only defeat the object of our Council in marking this letter ' private and confidential," and would bring about the very results which are shadowed in the earlier paragraphs of Dr Williams's letter

Needless to say, our Council is prepared to discuss the matter privately with any member who shares the views expressed in Dr. Williams's letter and we have no doubt that any fears that he may share with Dr Williams and his Society will be set at rest

We are Sir yours faithfully,
HERBERT F WATERHOUSE.
President
JAMES NEAL
General Secretary
Bedford-square, W C May 23rd, 1927

A POINT UNDER THE MIDWIVES ACTS

To the Editor of THE LANCET

SIR —Medical practitioners have recently been refused payment for assisting midwives in emergencies by the Devon County Council on the ground that the accounts for such assistance have not been sent in within two months from the date of the first attendance Reading Section 2, Subsection 2 of the Midwives Act 1926 and Section 14 Subsection 2, of the Midwives Act, 1918 together, it is a condition of payment of such fees that the accounts must be rendered within two months from the date of the first attendance and therefore strictly speaking the Devon County Council are within their rights as laid down by statute in refusing to consider a claim for fees under the Midwives Acts which are rendered after the two months statutory period

Unfortunately no notice of this regulation is conveyed to the medical practitioners and those who are not familiar with the Midwives Acts are consequently not aware that it is important to render their accounts as soon as possible Even if there are solid grounds for stringently requiring early rendering of such accounts it would seem to be only fair that due intimation of this most unusual condition should be communicated to the practitioners concerned

The matter is not one of interest to the medical profession only but also concerns the public very seriously, since the result of failure to obtain payment under such circumstances has led medical practitioners to decline in future to attend cases on the summons of a midwife It would be very unfortunate if this state of affairs should continue or extend

I am, Sir yours faithfully,
HUGH WOODS
General Secretary, London and Counties Medical Protection Society Ltd
Victory House, Leicester square, London, W C 2,
May 19th 1927

*** In the absence of official warning as to the regulations enacting the rendering of these accounts within two months it is hoped that practitioners will make a careful note of the above communication. The need for promptness insisted on by the Midwives Acts is due to the migratory nature of the constituency concerned —ED L

Correspondence.

"*Audi alteram partem.*"

MAZE TESTS AND SOCIAL ADAPTABILITY

To the Editor of The Lancet

Sir,—In your issue of Nov. 20th, 1926, there appeared an article by Dr. R. F. Jarrett which dealt in part with the application of my maze tests to 100 youths in the Borstal Institution. Following this article a letter from Dr. R. Evelyn Lucas was published which stated that:—

> "The Porteus 'maze' tests would hardly seem the best choice for determining the individual's apperceptive abilities. Their value lies in estimating powers of mental representation and planfulness in dealing with geometrical figures rather than with a concrete situation such as the individual is likely to meet with in ordinary daily life. To be sure Porteus himself claims considerably more than this for the test, but his statements have not been verified by other investigators. In my opinion, by far the most valuable test of this nature, and one which has a fairly high correlation with social apperceptions, is Healy's 'Pictorial Completion II.'"

The number of misleading statements included in this brief paragraph is such that it would seem desirable that a brief summary of the present status of the maze test be given for your readers who might otherwise be led astray by ill-informed or unsupported "opinions." In the first place, Dr. Jarrett was probably not concerned particularly with the individuals' apperceptive abilities. If, however, he was concerned with estimating, the tendency of his subjects to exercise planning and prudence in a simple situation or conversely to act impulsively or in a mentally confused manner when faced with a new problem, then probably Dr. Jarrett's choice of tests was a wise one. In any case he is not alone in this matter. A recent survey of mental clinics in New York State, by Boyakin[1] showed that over 40 per cent. of these clinics were using the maze test. The Pintner-Paterson scale was next on the list, and amongst the other 68 tests listed the combined percentages for Healy Completion I and II was 25 per cent. If, as your correspondent states, this test is so much more valuable than the maze it is evidently not as well known in America as it should be.

In the second place, your correspondent's description of the maze test as estimating "powers of mental representation of geometrical figures," would be recognised by any psychologist as being very inadequate, so much so as to make one wonder whether Miss Lucas has really had any experience at all with the tests. Such powers enter into an intelligent response to the tests to a very small degree unless the ability to trace a course with the eye for a few inches can be considered "mental representation of geometrical figures."

The further statement that I have made claims for the tests which have not been supported by other investigators is best answered by a brief summary of some of the literature evidently unknown to your correspondent. Morgenthau in "Some Well-Known Mental Tests Evaluated and Compared"[2] a monograph written with the advice of Drs. Healy and Bronner, comes to the following conclusion:—

> "The results obtained as to value of the tests were as follows. Stanford-Binet, Pintner, Alpha II and Porteus are valuable tests and should be included in individual case studies. In spite of their unmeasured reliability, Myers and Pictorial Completion II are also valuable tests, and should likewise be included."

She found that P.C. II and Porteus maze test correlated about the same with the Binet and rather highly with each other, the coefficient (0.70) being high enough to indicate a goodly measure of agreement and yet low enough to show that they are not both measuring the same capacities. This indicates that P.C. II is a very valuable test, but gives no shred of evidence for the opinion that it is far more valuable than the rest.

Arthur and Woodrow tried a number of performance tests with large numbers of clinic cases in St. Paul, U.S.A., and found that as regards discriminative value—*i.e.*, *power to distinguish* between ability at different chronological levels (as between eight and nine year ability for example)—the maze was among the best of the performance tests now available. Virginia Graham Taylor working with Jewish and Italian children obtained confirmatory data.

In an article, Comparison of Stanford and Porteus Tests in Several Types of Social Inadequacy, Cornell and Lowden's results confirm the claim that the maze tests are better measures of social adaptability than are the verbal tests. The constitutional psychopathic inferior group had a median Stanford-Binet of 13.25 years, as against 12.25 mental age score by the Porteus. A non-psychotic but mal-adjusted group had a Binet median age of 14.08 years and a maze score of 12.25 years—quite a significant difference. The so-called mentally defective group included cases on parole from institutions and they scored 10.21 years by the Binet, 11 years by the maze. Considering these high levels they were certainly not a typical feeble-minded group.[3]

In the Institute of Juvenile Research in Chicago, Worthington compared the maze with other performance tests and reported the results in an article, Study of Some Commonly Used Performance Tests. On the basis mainly of high correlation with the Stanford-Binet, inter-correlations, and normal distribution of results she picked four out of the eleven tests as being the best substitutes for a Binet Examination when this could not be applied. The four tests were Pintner-Toops, Seguin Form Board, Porteus Maze, and Trabue Completion.

In Frances Gaw's Study of Performance Tests[4] the introspections of seven psychologists who took the tests included the maze and Kelly's tests as the only tests of temperamental capacities. As regards the validity of the tests, that is to say actual proof that they do measure in part social adaptability, there are few studies, since to gather the necessary observations to serve as criteria is admittedly difficult. Elizabeth Ross working at Baldovan Institution found a correlation of 0.76 between Porteus age and ability in Handwork, the Binet mental age correlating with Handwork 0.69. In another investigation the Porteus correlated 0.81 with industrial rating of inmates, the Binet also 0.81, but the average of Binet and Porteus mental 0.87. Industrial capacity is of course an important factor in social adaptability.

Wildenskov has applied the tests at the Keller Institute in Denmark and confirmed results previously obtained by me (Porteus Labyrintskala, Nyt Tidsskrift for Abnormvoesenet). He states in his conclusions, that at the time of testing 100 inmates—

> "information was obtained of the practical ability of each individual from the people with whom they have been placed. A comparison shows that in the Porteus scale we have got a valuable addition to our test material."

Herring reports the results of a comparison between an experienced examiner's diagnosis of feeble-mindedness by means of observation of the child at work on the Porteus maze, plus the consideration of the Binet, Wilmer Form Board, Army Designs, case history, psychiatric and medical findings. He states that this diagnosis of degree of feeblemindedness practically agreed with the Porteus test results, a correlation of .937 being obtained.[5] As regards the validity of the tests for diagnostic purposes this evidence is of value.

Finally, as regards the application of these tests to delinquents, Doll in a paper entitled Education of Juvenile Delinquents[6] states:—

> "The Porteus motor intelligence tests should be applied whenever possible. Certain boys who may obtain high

to afford a satisfactory solution of the professional problems created by the establishment of the new Governments in Ireland. It is equitable as between autonomous Governments. It is practicable from an administrative point of view. Above all, it necessitates no change in the relations that have so long subsisted between the General Council, its Irish Branch Council, and the licensing bodies and medical practitioners of Ireland."

India

After briefly recording that the Legislature of the Province of Quebec had abrogated the 48th Section of its Medical Law, by which act practitioners registered in this country would henceforth be denied similar privileges in the Province, the President went on to refer to the visit paid to India during the winter months by Sir Norman Walker and Colonel Needham, on the invitation of the Secretary of State, with the concurrence of the Government of India and of the provincial authorities, which was successfully completed in March last. "The visit," he said, "was regarded as of deep importance for the future of Indian medicine and the Council's acceptance of the invitation addressed to its representatives had been rightly interpreted as attesting its sincere interest in India and its genuine wish to contribute to her progress in professional education. The Council owes a special debt of gratitude to its envoys for the way in which they have carried through their delicate and difficult mission, and for the happy impression of the Council's purpose and desire they have conveyed to the Indian authorities. They have now reported to the Executive Committee on those parts of their comprehensive survey that concern the immediate question before the Committee—namely, the continuance for a further period of the recognition granted to certain Indian medical degrees. A report of a satisfactory nature has been received regarding the efficiency of the Medical College at Singapore, and also reports dealing with Calcutta, and with the new universities of Rangoon, Patna, and Andhra, which call for detailed consideration. To these reports, and to certain larger questions of primary importance on which much has still to be reported, the Committee proposes to devote its July session. In particular it is imperative to discuss what steps can be contrived to maintain in India, for degrees that may be recognised for extra-Indian purposes, the standards of education and examination that are necessary to guarantee their sufficiency for registration and practice in this country. It is clear that recognition, renewed from year to year under conditions that cannot be fully complied with, does not afford a solution of the problem. The whole subject must be placed on a more satisfactory basis. The condition of periodic visitation and inspection through the direct agency of the Council is no longer practicable. The number of universities and medical colleges has greatly increased. They are scattered over a vast area from Bombay to Rangoon. And in future the high personal qualifications and ample experience of our present visitors may not be at our disposal. Thus it appears highly expedient that steps toward a new method should now be taken. These steps must originate in India, and we learn that Indian proposals bearing on the subject of central direction have already been under consideration by the Government and the Legislature. Whatever method is adopted it seems necessary for efficiency that it should be carried out as a function of Government or by some single authority in India with which the Council *could* communicate directly and from which it could obtain from time to time the information it requires to enable it to fulfil its duties under Part II of the Medical Act, 1886. In view of the commissions that will soon be set up to consider (inter alia) improvements in the machinery of Indian administration, it may be opportune for the Council to call the attention of the Secretary of State to the lacuna in medical organisation I have indicated. In order to give an opportunity for the initiation of improved arrangements in this regard the Executive Committee have at this session resolved to renew for one year more the recognition hitherto accorded to the medical degrees of Bombay, Madras, Lahore, and Lucknow."

Sir Donald MacAlister concluded by calling the attention of the Council, at the request of the Ministry of Health, to the fact that the Births and Deaths Registration Act, 1926, comes into operation on July 1st, and provides new forms enabling practitioners to furnish the precise information that is essential to the compilation of accurate medical statistics. The *President took the opportunity of warning medical* practitioners once again of the high importance which *the Council attached to accuracy in certification, as* shown by the Warning Notice.

A vote of thanks to the President was proposed by Sir Jenner Verrall and seconded by Sir Norman Walker, and the new members of the Council were introduced.

The Council acceded to the request of Mr. S. Cosgrave to have his name restored to the Dentists' Register, and later proceeded to the hearing of penal cases.

THE LISTER INSTITUTE.

ANNUAL REPORT FOR 1926-27

IN the annual report of the Lister Institute, presented at a general meeting on May 18th, reference is made to its incorporation as the British Institute of Preventive Medicine in 1891. Lord Lister took a leading part in its establishment, was the first chairman of council, and later president, and never ceased to take an active interest in its development. These facts were recalled in the address presented on the occasion of the Lister centenary last month by Sir James K. Fowler, who represented the Institute at the ceremony.

The report for the past year chronicles but few changes in the governing body, council, or staff. Dr. Andrew Balfour takes the place of the late Sir William Leishman on the council. The resignation of Dr. E. Atkin from the position of assistant bacteriologist is recorded, on his appointment as pathologist to the Brompton Hospital. Dr. J. A. Arkwright, F.R.S., has resigned his position as a salaried member of the staff of the bacteriological department, but will continue to work in the department, where Dr. H. B. Maitland has been appointed as an assistant.

The continued cooperation between the Institute and various other bodies is noted with appreciation. The financial support given by the Medical Research Council, the Department for Scientific and Industrial Research, and the British Empire Cancer Campaign to skilled investigators in the different departments has greatly increased the scientific activities of the Institute. A summary is given of the research work accomplished and in progress during the year. Altogether nearly 50 papers have been published from the five departments of the Institute, whose activities are outlined below.

Department of Bacteriology

In continuation of his work on the relation of vaccinia virus to the reticulo-endothelial system Prof. J. C. G. Ledingham has published a new series of experiments, the results of which show that the dermal reaction to the virus is annulled wholly or partially if Indian ink is simultaneously injected into the cutis with the virus or if the virus is superposed on sites previously infiltrated with Indian ink.

It would appear that the absence of naked-eye response to the virus under these conditions is to be correlated with the increased local defence following the *stimulation of the* reticulo-endothelial system by the Indian ink. The experimental results support the view previously advanced that the virus of vaccinia (or of variola) attacks primarily the reticulo-endothelial elements wherever situated *and not* epiblastic or epidermal elements as has been alleged. It may be noted also that vaccinia failed to elicit response in *the cutis of the* rabbit which had previously been the site

THE NATIONAL UNION OF SCIENTIFIC WORKERS

To the Editor of THE LANCET

SIR,—In an annotation which appeared in your issue of March 19th it is suggested that the National Union of Scientific Workers will find insuperable the difficulty of combining scientists in different lines of work. There is much to be said on the other side, but it is not my present purpose to say it; my object is merely to protest that you might have expressed that opinion without insulting the members of a profession as honourable as your own. You contrast university teachers with "those whose object in life is (or from their occupation ought to be) to earn dividends for shareholders," and in the next sentence make a veiled suggestion that these are comparable with those who would exploit medical discoveries for private gain. Your remarks are pointless unless they are interpreted to mean that industrial scientists take a different and less worthy attitude towards their work than their academic colleagues.

It is as ignorantly foolish to suggest that industrial scientists are engaged in manufacturing dividends as to suggest that the medical profession is battening on the miseries of mankind. It is true that in the present economic organisation of society, if there were no dividends there would be no industrial scientists, just as if there were no disease there would be no doctors. But to pretend that the ultimate results or necessary conditions of work are among the prime motives which determine the undertaking of it is a psychological fallacy that no intelligent person should commit. Most industrial scientists are not communists and may therefore hold that the earning of commercial profit is not inconsistent with service to the community. They may even hold reasonably that their work is likely to reduce rather than increase the divergence of interest between its sections. Nor is knowledge necessarily uninteresting because it is commercially valuable. It is as possible for the industrial worker to be inspired by a real love of his work for its own sake, and indeed as necessary to his success, as an elementary lecturer in a university or a panel doctor.

Writing for and on behalf of the G.E.C. Branch of the N.U.S.W., I am indeed prepared to maintain that, since the industrial scientist is usually a member of a team and free from temptation to an exaggerated individualism, his motives are usually purer and less self-regarding than those of the academic scientist. Doubtless our profession, like any other, including that of medicine, has its black sheep. But to pretend that the association of science with commerce must necessarily degrade the former rather than elevate the latter, is a despairing pessimism which is utterly unjustified by the facts.—I am, Sir, yours faithfully,

BERNARD P. DUDDING, A.R.C.Sc.,
F.Inst.P., M.B.E.,
Hon. Secretary of the Branch.
Research Laboratories of the General Electric Co., Ltd.,
Wembley, May 18th, 1927.

*** A medical man may not limit in any way the application of a fact which may prove useful to other medical men. The industrial scientist is under no such obligation and is entitled to demand, from employers or the community, a reward commensurate with the importance of his work. The National Union setting out to improve the status of the scientific worker must be prepared to support the claim of an inventor for adequate reward from his employer. In a conflict of this kind the medical man could not be engaged; he strives on the understanding that there will be no special payment for success, and that no information will be held up by him in the absence of direct returns. The university teacher or research worker adopts the same convention, because his investigations are undertaken at the expense of a body which has been endowed with the sole object of advancing knowledge. But a nation which honours its scientific discoverers honours itself.—ED. L.

GENERAL MEDICAL COUNCIL.

THE PRESIDENT'S ADDRESS

THE summer session of the General Medical Council was opened on May 24th, Sir DONALD MACALISTER presiding. After noting with regret the death of Sir Isambard Owen, the President made reference to the retirement of Sir Nestor Tirard and Sir E. Coey Bigger, the Crown members for England and Ireland respectively, whose terms of office had expired. He recorded the valuable assistance rendered to the Council by the former for 32 years in connexion with the Pharmacopœia, as Secretary, Reporter, and Medical Editor, and as representative of the Council on national and international committees. To Dr. H. H. Dale, the new Crown member in Sir Nestor Tirard's place, the President extended a cordial welcome, alluding to his great eminence in the application of pharmacological and biochemical science to medicine, and to his administrative experience in many fields, as secretary of the Royal Society, and head of the department of biochemistry and pharmacology in the Medical Research Institute. Sir E. Coey Bigger's retirement, the President pointed out, was a consequence of the establishment of the Irish Free State, in which he is now a senator and chairman of the Public Health Council. Colonel Thomas Sinclair, M.P., a senator of Northern Ireland, who takes Sir E. Coey Bigger's seat as a Crown member, is already the representative on the Council of Queen's University, Belfast, so that for the time being the seat for that University is vacant. The President further reported that Sir Humphry Rolleston, formerly representative of the Royal College of Physicians of London, had become the representative of the University of Cambridge in place of Dr. W. L. H. Duckworth, while the College had sent to the Council a worthy successor in the person of Dr. Farquhar Buzzard, whose football record he did not forget to mention while valuing him as a neurologist.

Ireland

The President continued: "I mentioned last November that the Medical Act, 1926, of the Irish Free State would expire in February, 1927, unless fresh legislation was carried through. A Medical Act, 1927, was accordingly passed in that month to enable the existing arrangements to be continued until June 21st, 1927. In the meantime, conferences have taken place between the Governments of Great Britain and Northern Ireland and the Free State, at which I was courteously invited to be present. These have happily resulted in an agreement which has been signed on behalf of the three Governments, has been ratified by the Free State legislature, and now awaits parliamentary ratification in this country. It provides that the Medical Acts hitherto in force in Great Britain and Ireland shall continue to apply to the Free State, as concerns the functions, constitution, powers, authorities, and jurisdiction of the General Medical Council and its branch councils. It provides that the direct representative for Ireland shall continue to be elected by the registered practitioners resident in any part of Ireland, and that the Crown member for Ireland shall be appointed by His Majesty in Council on the recommendation of the Governor of Northern Ireland. And it ensures that practitioners registered in the Medical Register shall be entitled to be registered and to practise in the Free State. By an Act of the Oireachtas a Free State Medical Council has been established to maintain a local medical register distinct from the General Register, and to exercise in regard to it a jurisdiction distinct from that of the General Council. But the jurisdiction of the General Council in Southern Ireland will not be displaced or diminished for any purpose of admission to or removal from the General Register, or of maintaining the standard of professional education and examination in reference to registrable qualifications granted in Ireland. The provisions of the agreement appear to me, after careful and indeed anxious consideration, of the blood under physiological and pathological conditions are in progress

Dr J O W Barratt's observations on the anticoagulant effect of hirudin have been completed The experimental results obtained indicate that the interaction of hirudin and thrombin corresponds to that of weak acid upon weak base and show that the hypothesis of an absorption of thrombin by hirudin is untenable The experiments made also show that both hirudin and thrombin are present in true solution in the concentrations employed

Prof V Korenchevsky, in coöperation with Miss M Schultess-Young, is attempting to isolate the specific sexual hormones

He has also studied the influence of the removal of the thyroid, parathyroid, and sexual glands and of thyroid feeding on the regulation of the body temperature After thyroidectomy, cooling causes a much more pronounced fall, and warming, a much less increase of the body temperature than is observed in normal animals Prof Korenchevsky concludes from his experiments that the thyroid gland plays an important part in the regulation of the body temperature, and therefore its condition has always to be taken into account in considering the resistance of different individuals to cold or heat and also in the diseases accompanied by fever

Miss E M Hume and Miss Henderson Smith have been engaged in a lengthy research with the object of improving the technique of estimating vitamins A and D, and new methods have been devised

Since the introduction of a new technique for estimating vitamin A it has become necessary to revise many old determinations Yeast fat is now found to be deficient in vitamin A, and the vitamin D value, both before and after irradiation, of different samples of yeast fat, which has a high content of ergosterol is now being studied The previous work of Dr Harriette Chick and Miss Margaret H Roscoe showed that the green leaves of spinach (*Spinacia oleracea*) while a rich source of vitamin A, contained vitamin D in small amount only, even when grown in spring and summer under maximal natural illumination Nevertheless, as Hess first showed, similar leaves after short exposure to ultra-violet irradiation from a mercury arc lamp acquired high antirachitic value The strikingly different effect of sunlight and the radiations from a mercury arc might be associated with the much greater intensity of the smaller wave-lengths in the latter or the disappearance of vitamin D from green leaves almost as quickly as it is formed To test the latter hypothesis Miss Roscoe has grown spinach and gathered it in sunshine and fed it immediately to the experimental animals Under these circumstances, however, spinach was found to possess only a just detectable antirachitic value It would appear from the recent discoveries of Rosenheim and Webster, and Hess and Windaus that the first explanation is the correct one They found that vitamin D is activated ergosterol, which substance has a specific absorption for radiant energy of a wave-length absent from sunlight but present in the radiations from the mercury arc

Marine green organisms such as *Nitzschia* can no longer be regarded as the ultimate source from which the cod and other fish obtain the antirachitic vitamin stored in their liver oils, Miss Leigh-Clare has been unable to detect the presence of vitamin D in *Nitzschia*, whether the diatom was grown in the laboratory behind window-glass or on the roof of the Institute, protected with a covering of windolite, a material fairly transparent to ultra-violet light of the refrangibility occurring in sunlight Miss Leigh-Clare has also examined the stomach oil of the mutton bird or Australasian petrel (*Œstrelata lessonii*) for its content of vitamin D and has found it present in a concentration equal to about one-fifth that found in a good cod-liver oil The interest of this investigation lies in the fact that the mutton bird is believed to consume the same food as the Australasian red cod—i e , a crustacean known as " whale feed "

A comparison of biological and colorimetric methods of titrating vitamin A was undertaken at the request of the League of Nations Conference on Standardisation of Biological Values at Geneva in 1925

The results of biological titration by the different laboratories of material provided indicated a large experimental error, but nevertheless showed the vitamin A value of various samples of Norwegian cod-liver oil to differ from one another by as much as one hundred fold The results of the colorimetric titration of any one oil by the method of Drummond and Rosenheim agreed with the series of values obtained by the biological method in the different laboratories, as nearly as the latter agreed among themselves At the Lister Institute the work was entrusted to Miss Soames, assisted by Miss Leigh-Clare These workers titrated the antirachitic value of the oils in addition to that of vitamin A with the interesting result that among the whole series of oils the former was found to be much more uniform than the latter This is possibly attributable to the fact that the oils were no longer fresh and vitamin A is much more unstable than vitamin D

Dr Chick and Miss Roscoe have confirmed the recent work of Goldberger and his colleagues, which indicated that " water-soluble B " must be regarded as a combination of the antineuritic vitamin with a second factor, probably identical with the principle in diet which prevents pellagra The work is being continued by a study of the distribution of these two principles (*a*) " antineuritic " and (*b*) " anti-pellagra " and an attempt to separate them when present together in various rich sources of vitamin B

A method has been evolved which permits of accurate observations on the nitrogenous metabolism of small animals—e g , rats—and Dr Chick and Miss Roscoe are making re-determinations of the relative values of some of the more commonly occurring proteins for maintaining nitrogenous equilibrium in the rat It is proposed to examine a series of proteins in their natural as well as purified state and to extend the investigation to naturally occurring nitrogenous substances of a non-protein nature

Dr Margaret A Boas (Beit Memorial Research Fellow) has continued her study of the influence of dehydration on the nutritive properties of egg-white

With regard to the biological action of light, Hess showed that rickets could be prevented or cured by feeding with the cholesterol esters in the skin (lanolin) after irradiation with ultra-violet light, and suggested that a possible source of vitamin D was the absorption of lanolin which had been activated by sunlight Miss Hume, Dr Lucas, and Miss Henderson Smith have experimentally tested this suggestion

Young rats and rabbits were placed upon a diet on which they would inevitably suffer from rickets 0 2 g of irradiated cholesterol in hardened cotton-seed oil was applied daily to an area of depilated skin equal to about 1 square inch, every precaution being taken to prevent the animals ingesting any of the material The treated animals did not develop rickets, the controls did Whether, owing to the opacity of the skin to ultra-violet rays, vitamin D is able to be formed only on its surface or whether sufficient of the activating rays penetrate the epidermis to activate any ergosterol which may circulate in the superficial capillaries is being investigated

Dr Lucas has also been determining the transparency of skin from different parts of the body to ultra-violet light of wave-lengths varying from those of visible light to the shortest that occur in sunlight

Miss Hume, Dr. Lucas, and Miss Henderson Smith have also made some interesting observations on the beneficial action of a short daily exposure to ultra-violet light on the well-being of marmosets These animals fare badly in this country, refuse a diet suited to our climate, and rarely breed here The marmosets under investigation have been kept in a stuffy room into which no sunlight penetrates that has not passed through plate-glass They have been fed chiefly upon sweetened milk and bananas and exposed for ten minutes daily to the rays from a mercury arc lamp They have enjoyed perfect health and are extraordinarily active and have bred twice in the year The offspring were well-developed, but each time one of the twins was born dead, the other flourished

Dr T Lumsden, with the assistance of Miss A C Kohn-Speyer, has continued his work on implanted homologous malignant tumours in animals published in THE LANCET, 1926, ii , 112, and Jan 15th, 1927, p 116 Experiments with heterologous tumours are in progress

Department of Protozoology

Dr Muriel Robertson has been occupied with a morphological study of the two organisms *T ranae* and *Bodo caudatus*, with special reference to their method of division and to the nature of the parabasal body Dr H M Woodcock (Jenner Memorial Student) is continuing his work on encephalitis of rabbits of an acute inflammatory process caused by injection of erysipelas streptococci It is of interest in this connexion that failure of vaccinial response has been recently reported on rabbit skin which has been exposed to X ray and ultra-violet radiation

Dr Emerson Megrail (Western Reserve University, Cleveland, Ohio) has commenced a series of experiments to test the filterability of avian molluscum through porcelain and kieselguhr filters and collodion membranes

Dr Arkwright has continued his study of variation of the virulence and antigenic structure of bacteria Latterly his observations have been more particularly concerned with *B typhosus* and *B paratyphosus* A and their antigenic constituents

He has studied the properties of the two main kinds of antigen in the coli-typhoid group of bacteria—namely, the heat-labile and the heat-stable at 100° C, concluding that virulence and value as a vaccine are both related to the content of the heat-stable antigen That this antigen is the constituent which gives efficacy to a vaccine was supported by the finding that the vaccines after heating at 100° C had, as a rule, unimpaired prophylactic value The results with *B typhosus* vaccine were in the same direction but less distinct These observations will be extended

Dr Dorothy B Steabben has begun an experimental study of the antibodies corresponding to the heat-stable antigen in the typhoid-paratyphoid group With Dr. Arkwright's recent work on *B pseudotuberculosis rodentium* our readers are familiar (THE LANCET, Jan 1st 1927, p 13) The motility of cultures of this bacillus when grown at room temperature and their non-motility when incubated at 37° C serves to distinguish the bacillus from *B pestis* Dr Balteanu (Rockefeller Foundation Fellow) has completed his study of *V choleræ* and established the existence of variants with characteristic antigenic differences corresponding to the "H" and "O" antigens in the coli-typhoid group These two antigens have been found to be present regularly in the cultures of the normal form, contrary to the opinion of most previous workers

The action of cyanides on bacteria has been studied by Dr F M Burnet (Beit Memorial Research Fellow) who has also been engaged on a study of types of bacteriophage active against *B enteritidis* (Gaertner) with a view to their use in the treatment of infections in animals by this organism Very characteristic differences between the action of various types of phages on bacteria grown from smooth and rough forms of colony have been found

Dr G H Eagles (Beit Memorial Research Fellow) has extended his work on hæmolytic streptococci from scarlatina, erysipelas, and puerperal fever

Using commercial scarlet fever antitoxin he has found by testing in the human volunteer that all toxic filtrates, regardless of source, are neutralised Antitoxic sera produced in rabbits by strains from each source tend to show some specificity in their power of neutralisation which would probably disappear from the serum in the later stages of immunisation Immune horse serum produced by inoculation with toxin-producing strains of erysipelas show a considerable degree of neutralising value for streptococcus filtrates, including those from scarlet fever strains The possibilities of using intracutaneous tests in goats to avoid the use of human volunteers has been investigated. This has not proved a satisfactory method owing to the high susceptibility of these animals to horse serum An attempt is, therefore, being made to produce an antitoxic scarlatinal goat serum When this is ready it is hoped to come to a definite conclusion regarding the goat as a test animal

Dr H L Schutze has commenced investigations of the pasteurella group of bacteria and of the oxygen requirements of *B pestis*, and has concluded his joint work with Dr S S Zilva on the effect of diet upon the course of tuberculosis in animals

Guinea-pigs *living on a diet restricted* in quantity were found to be considerably less resistant to the progress of a tuberculous infection than normally fed controls Experiments on rats produced *no evidence* of a beneficial effect of sodium chaulmoograte as shown by the course of the development of tuberculous tumours in these animals On the other hand, there was some evidence for assuming that a large excess of cod-liver oil, as well as irradiation with ultra-violet light, did inhibit the formation of such tuberculous tumours The leucocytosis often observed under these two forms of treatment does not seem to be the only agent in this inhibition, if it is concerned with it at all

Mr Bruce White, under a grant from the Medical Research Council, has undertaken serological studies of the salmonella and dysentery groups of bacilli, and is working on the classification of intestinal bacilli along new lines

Dr D Kalic (Rockefeller Foundation Fellow) has investigated the typing of dysentery bacilli

Major J H Horne, I M S, has been investigating the distribution and method of spread of furunculosis in trout, on behalf of the Kennet Valley Fisheries Association

Department of Biochemistry

The reaction which occurs between sugar and phosphate in the course of alcoholic fermentation has been investigated quantitatively by Prof. Harden and Lord Henley, with special reference to the quantities of the mono- and di-phosphoric esters produced The work commenced last year by Miss Edna C Smith on the conversion of starch into cane-sugar, when potatoes are stored at 0° C, has been continued Another aspect of the same general problem is being attacked by Miss M J Macfarlane, who has commenced an investigation on the function of phosphates in bacterial fermentations to ascertain whether the breakdown of the sugars by these organisms is effected in a similar way to that produced by yeast

The chemical constitution of hexosemonophosphate and hexosediphosphate has been studied by Mr W T J Morgan (Grocers' Company Research student) He has also, in collaboration with Mr H P Marks at the National Institute for Medical Research, investigated the effect of these substances on rabbits and mice suffering from hypoglycæmia as a result of the administration of insulin No alleviation following administration has been observed

The phosphoric esters which occur in the blood and other animal tissues and the enzymes by which they are synthesised and hydrolysed in the body have been the subject of Dr R Robison's work In collaboration with Dr M Martland, he has made an extended study of the properties of the bone enzyme (phosphoric-esterase) and the results are now being prepared for publication The conditions of calcification in vitro have *also* engaged his *attention* Continuing his chemical investigations of the antiscorbutic factor, Dr Zilva has succeeded in improving the methods for fractionation of this vitamin

Antiscorbutic tests have been carried out on the duplicate sample of stored lemon juice taken out by the *William Scoresby* to the Arctic circle last year No appreciable loss in activity could be detected after 12 months' storage Systematically collected whale liver received from Dr Kemp of the *Discovery* expedition has been tested by Dr Zilva for its content of vitamins A and D In collaboration with Miss Soames and Captain J Golding of the National Institute for Research in Dairying, Dr Zilva has found that by adding cod-liver oil to the diet of the cow, the butter acquires enhanced vitamin D and vitamin A activity, whilst addition of green fodder leads only to improvement in the vitamin A content This investigation is being extended further and clinical experiments are being conducted by Dr Helen Mackay

Dr Smedley MacLean and Mr C G Daubney have studied the synthesis of fats sterols, and lipins by vegetable organisms

Department of Experimental Pathology

Prof C J Martin and Dr Elizabeth Lepper have continued to study the aberrations of the colorimetric method of determining pH caused by the presence of various substances Their results explain some of the contradictory results obtained by previous observers when using neutral red to determine the reaction of sera Dr E Lepper and Dr M Martland have made observations on the alterations produced in the hydrogen-ion *concentration of* the blood during forced breathing, which at the rate of 40 per minute increases the pH of the blood 0 2 short but violent exercise lowers the pH 0 1 or more These and other experiments on the variation o the alkalinity

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Trade Disputes Bill Labour Criticism of Medical Profession

On Monday, May 23rd, the House considered in Committee the Trade Disputes and Trade Unions Bill

On Clause 3 (which deals with the prevention of intimidation),

Sir H. Slesser said that there had been cases in which the British Medical Association had told doctors that if they took salaries lower than a certain rate at infirmaries no other doctor would be allowed to consult with them There was the case of Pratt v British Medical Association in which the British Medical Association for telling doctors that they might not consult with Dr Pratt at Coventry were fined £1000 or £2000 in damages Case after case of professional coercion had occurred, and if the Government were really so apprehensive of intimidation and coercion of all kinds, so sensitive about the mind of man being coerced by any external power, if they once departed from what he (Sir H Slesser) thought was the salutary principle of limiting the application of the Statute to preventing violence and threats of violence, he asked why should they stop at the working man? There were thousands of private employers who would welcome a provision which would protect them against the tyranny of employers' combines

Mr Macquisten said he did not understand the morale of picketing at all If he personally were picketed it would take a good big crowd of his fellow lawyers to carry it out with any success (Hon Members · "What about doctors?") It was all very well to talk about the doctors He was quite in agreement with hon Members that doctors had far too much power He thought that the British Medical Association was the most tyrannical trade-union the country possessed, and he would be delighted to see some clause introduced which would prevent these trade rings from victimising the whole community They would have to be dealt with some time or other

Mr Lawson said that he thought this clause was not only an injustice to the great mass of the workers, it was not only an example of class vindictiveness, but it was the most perfect piece of hypocrisy that had even been brought before the House What they were doing was to punish workmen for doing certain things which everyone in the House knew were done by every class and profession in the country Dr Vernon Davies, who was a member of the medical profession, had asked him (Mr Lawson) what he thought of the recent speech of Mr Spencer He had replied · "What would happen to him if he had been a doctor instead of a miner, and if the British Medical Association instead of the Miners' Federation had been dealing with him?" He would have been driven out of the medical profession There was a celebrated case which commanded the interest of the whole of the press and the whole British public and in spite of the fact that it was universally agreed that Dr Axham was intimidated, the British Medical Association not only carried on its work in regard to him but did it with legal authority In the mining areas they had not always the kind of medical service which they considered good enough, and they had brought in doctors They had given them infinitely better salaries than they were getting elsewhere; they had given them better instruments and medicine, but in spite of that he did not know a single case where the British Medical Association had not stepped in and used threats to prevent those doctors practising under those conditions

Dr Vernon Davies Do I understand the hon Member to say that the British Medical Association have definitely threatened these men or that they have simply offered advice to them not to undertake the work?

Mr Lawson replied that these professional men had been "advised" They had been brought down to meet representatives of the British Medical Association in the country They had put their case and defended themselves, and there was not a single case where they had not been driven out and intimidated

Dr Vernon Davies said that Mr Lawson seemed to be suffering under some slight misapprehension in his remarks concerning the British Medical Association The British Medical Association was not a trade-union It was a voluntary combination of a certain number of medical men, but there was no compulsion upon any man to join, and any man who did join was not compelled to obey their rules and regulations He had been a member of the Association ever since he went into practice, and as often as not he had been opposed to their policy In the House he had voted against their policy on Committee, and yet he had not been penalised in any shape or form, threatened or interfered with. He had given his point of view and said that as he believed they were wrong he should vote against them, and he had done so and had not suffered Cases were mentioned where the British Medical Association had interfered with certain appointments All that the British Medical Association did was this They said "We are an association of medical men out to protect the interests of the medical men and the public We think a certain job is worth a certain amount of money. This particular society or company is advertising a job at a rate of remuneration which we think is too low. If you accept it you will be very foolish, because if you stick out you can get more." Suppose a man took it, nothing was done to him All that the British Medical Association did was to say "You are satisfied with a lower rate, we cannot interfere, we cannot penalise you, and we cannot turn you out of the Association, nor can we advise anybody to have nothing to do with you"

Mr Lawson They drive him out

Dr Vernon Davies Not at all, that is where hon Members make a mistake All that the British Medical Association do is to say "You are fools if you are prepared to work for a lesser wage," but they cannot and do not penalise that man in any shape or form

Colonel Watts-Morgan asked Dr Davies to take it from him that he could give him a case of four doctors who had accepted appointments and had been boycotted by all the medical men in the district, who had refused their assistance in operations and in cases in hospitals If that was not intimidation, heaven knew what intimidation was!

Dr Davies said that he was referring to the British Medical Association It might be that the local doctors considered that a man who accepted this appointment was doing what would bring down the rates of remuneration, and they might say "We do not approve and, socially, we will not meet you." But, professionally, they were bound to meet him If any doctor refused to assist his professional brethren who might have any consultation he would not secure the backing of the British Medical Association, *or of any* medical man

Colonel Watts-Morgan I am quite prepared to give the hon Member the names so that he can *prove my statement*

HOUSE OF COMMONS

Wednesday, May 18th

Polluted Milk

Mr Buxton asked the Minister of Health (1) whether he was aware that medical officers of health in certain areas had given public advice against the consumption of liquid milk by infants, on the grounds of impurity, in their administrative area, and, in view of this fact, what further steps he proposed to promote a clean supply; and (2) whether, in view of the circular to the local authorities discouraging them from applying too zealously the Milk and Dairies Order 1926, what alternative steps he was taking to safeguard the public from the supply of polluted milk.—Sir Kingsley Wood replied · My right hon friend's attention has not been drawn to any recent instance of public advice being given by medical officers of health against the consumption of liquid milk by infants The right hon gentleman has not accurately presented the *purport* of the circular to local authorities as to the Milk and Dairies Order The circular emphasised the importance of insisting on cleanliness in milk production, and if the statutory requirements are observed and the Order is administered as suggested, my right hon. *friend* does not think that further measures should prove to be necessary.

Mr Buxton · Is the Parliamentary Secretary aware that in the House of Lords Lord Bledisloe alluded to the occurrence of medical advice of this character quite recently, and can he assure the House that the Minister of Health will resist any essential modification of the provisions of this Order?

Sir Kingsley Wood · I have no knowledge of the first statement of the right hon. gentleman. As regards the second that is, of course, a purely hypothetical question which I am not in a position to answer So far as the Order is concerned the views of my right hon. friend are represented in the circular which he circulated on Jan. 20th last

Mr Paling . May I ask whether the Order discouraging *local authorities* from carrying out these provisions was sent out as a result of protests of agriculturists on the Government side of the House?

Sir Kingsley Wood The hon. Member has no right to characterise the circular in that way There is no reference in the circular to any such statement

Commander Williams · Is it not a fact that the real danger is not from British milk, but from imported milk?

Mr Day · Has the Parliamentary Secretary seen the report of the medical officer of health for Woking, and if not, will he have that report looked at?

Sir Kingsley Wood · I am not aware of that report

Mr A. V Alexander: As it is impossible to get clean milk for a large number of the working classes without getting dried milk will the Minister of Health consider

It is characterised histologically by small-celled perivascular infiltration and the occurrence of focal lesions, constituted in part by large epithelioid cells Clumps of the small bodies, thought by some to be parasites, and called "*Encephalitozoa*" are found either associated with these zones or separate from them The disease occurs "spontaneously," at times in the form of an epizootic, both in America and on the continent, but very seldom in this country Kling, of Stockholm, considers that he *has produced the condition by inoculating rabbits* with material from cases of human encephalitis Dr Woodcock, working with material kindly sent by Prof Kling, has succeeded in obtaining infection in 20 per cent of the animals so far inoculated In these cases the "*Encephalitozoon,*" bodies found are identical with those previously found in a stock rabbit, when these bodies occur, well-marked lesions are also present, but characteristic lesions may occur without the bodies being found Both Kling and Woodcock are of opinion that these elements are not microsporidian parasites *and regard them as cell reaction products*

Dr Woodcock is also investigating the pathology of sarcocystic disease of the mouse

Department for the Study and Preparation of Antitoxic Sera.

Work on the standardisation of antidysentery serum has been carried on throughout the past year The *relation of "roughness" and "smoothness" of* streptococcus cultures to their virulence and hæmolytic power has also been studied in this department

Other investigations include those into the endotoxin of the plague bacillus and the production of diphtheria toxin An attempt has been made to combat pneumococcal infection amongst guinea-pigs by giving the animals a more generous ration of green food

Until Christmas the health of the stock remained exceptionally good, but during the early part of the present year a number of litters were born dead and some of the young died soon after birth The antenatal mortality and the deaths among the very young were found to be due to the pneumococcus Whereas formerly the mothers of the infected young *often died about a* week after parturition with an acute *pneumococcal* infection it *is* now exceptional for them to die in this period, they are in fact healthy carriers of the disease, which they transmit to their young It is suggested that some essential factor is missing in the nutrition of the fœtus by the mother's blood, a constituent which is gradually exhausted during the first half of the winter, and that the absence of this substance is less harmful to the parent than to the young It is natural to think that the missing element is vitamin D and it is proposed, during next winter, *to* artificially illuminate some of the breeding stock, with a suitable *control, in order to test the validity of this hypothesis*

The accidental production of pneumococcal endocarditis in a horse that was being actively immunised against a type 1 strain of pneumococcus led to the recovery from the blood of a strain of pneumococcus which proved to be non-virulent for mice Experimental work with this strain is in progress in the attempt to throw light on the pathogeny of acute and chronic endocarditis in man

In the department for the study and preparation of antivariolous vaccine Dr A B Green has made further *attempts to cultivate the vaccine virus artificially*, and has continued his work on the raising of the virulence of vaccine The recent progress of foot-and-mouth disease research *was recorded in the second progress* report of the Committee published early in 1927 (THE LANCET, March 5th, 1927, p 499)

General and Financial

A request from the Empire Marketing Board to the Medical Research Council for advice as to the best means of promoting an investigation into methods of preserving Empire fruits, vegetables, and dairy products in order to preserve their vitamins was, in November last, referred to the Accessory Food Factors' Committee, appointed jointly by the Institute and the Medical Research Council The Committee suggested that such an investigation be carried out at the Institute The Committee's recommendations were approved by the Medical Research Council and the Empire Marketing Board, and the Governing Body of the Institute The investigation will occupy five years and is being carried out in the Biochemical Department under the general supervision of Prof Harden. Dr S S Zilva will be in charge of the investigation and the cost of the inquiry will be borne by the Empire Marketing Board The accounts and balance sheet for the year ended Dec 31st, 1926, show balances to the credit of the pension fund of £23,041, the sinking fund of £15,258, and the capital fund of £506,792, the latter figure including the credit balance of £8481 from the year's working Receipts from the sales of the Institute's products and investigation fees show a net decrease of £4131 compared with the previous year—viz, antivariolous vaccine decrease £2156, antitoxins and sera decrease £1622, bacterial vaccines decrease £1160, investigation and diagnosis fees increase £808 The total expenditure for the year was £38,086, against £36,502 in 1925 Rent, rates, taxes, and insurance, repairs and renewals (including the installation of electricity at the serum department), and library expenses show an increase, and gas, water, and fuel, electric light and power, serum and calf laboratories expenses and animals a decrease compared with last year

The Services.

ROYAL NAVAL MEDICAL SERVICE

Surg Lt -Comdrs: O J M Kerrigan to *Impregnable*, J J Carroll to *Tamar*, addl, and for Hong-Kong Dockyard

ROYAL ARMY MEDICAL CORPS

Capts to be Majs C H G Penny (Prov), and H E P Yorke

Lt (on prob) H McVicker is confirmed in his rank

W F *Cooper to be Lt (on prob)*

J D Dillon to be Temp Lt

RESERVE OF OFFICERS

Col H G Martin, late R A M C, having attained the age limit of liability to recall, ceases to belong to the Res of Off

SUPPLEMENTARY RESERVE OF OFFICERS

Lt N M Maclennan resigns his commn

TERRITORIAL ARMY

Capt R R Evans, R A M C, to be Divl Adjt, 55th (W Lan) Div, vice Capt B L Davis, vacated

Lt L C F Chevens resigns his commn

TERRITORIAL ARMY RESERVE OF OFFICERS

Lt -Col A W Moore from the Active List, to be Lt -Col

Maj J Wallace, from the Active List, to be Maj

ROYAL AIR FORCE

Squad-Leader R S Topham is placed on the retired list at his own request

Flight Lt H H R Bayley relinquishes his temp comm on completion of service

INDIAN MEDICAL SERVICE

Capts Rustam Merwan Kharegat and J C Pyper to be Majs

Lt J C Drummond (prov) to be Capt

The Admiralty invites applications for short service commissions as surgeon-lieutenant and also as dental officers *Particulars may be found in our advertisement* columns
